- **1st phase**: Selection of the aspects/parameters to evaluate attending to the overall goals, identification of the metrics that will guide the evaluation for each aspect considered and also the identification of the context

variables that can affect the aspects that will be evaluated and the possible cause/effect relations of these variables;
- **2nd phase**: Determination of absolute or comparative levels that must be reached to guarantee that the objectives were satisfied;
- **3rd phase**: Data gathering about the selected aspects;
- **4th phase**: Data integration and analyze.

Our evaluation objectives were defined as follows:
- Assure that the students have learned in an enjoyable way to them;
- The technological tools used were not a barrier and permitted the desirable communication;
- Guarantee that the contents were sufficient and adequate to their success.

In the first phase, we decided which aspects are relevant to our evaluation objectives. We selected five aspects:

1. **Content quality** – All items from the discipline program have to be covered with clarity and the adequate rhythm – but also in an interesting way that could motivate the students. The contents presentation has to follow a consistent and an intuitive design.
   It is important to provide a rich learning experience to the students but this is not obtained by simply providing more and more online information to them. It is necessary to assure that they will use and interpret the available information to construct their knowledge. For instance, by delivering frequently assignments for students to discuss and solve. Usually these exercises originate the posting of a lot of messages in the discussion forums, some of them answered by other students.
2. **Technological efficiency** – This aspect can be a source of frustrations for the students. Volery (2000) classify this aspect as one of the most important variables that can affect the effectiveness of online delivery. We want to assess if the technological tools used in a course are robust, reliable and easy to use.
3. **Communication effectiveness** - According to Law (1997), there is evidence that distance education permits an effective learning with intellectual and emotional improvements. Teaching cannot be simply deliver materials and for this aspect we essentially want to measure the involvement of the students and the created interaction, factors that stimulate the clamping of knowledge (Daniel, 1996).
4. **Students' satisfaction** – Teaching is not only concerned with student satisfaction, but this aspect matters. The fact that the user continues in a system is sufficient to assure some satisfaction since in an absence of any satisfaction, students drop out the system (Silva, 1999). The number of students that drop out compared with previous instances of the course can be used as a measure of their satisfaction. It is also recommended to collect students' opinions.
5. **Students' success** – The learning outcomes of the students has to be measured. The number of successful students (compared with earlier courses) is not the only evaluation measure. Before the beginning of a course, it is needed to analyze their previous qualifications and complete an individual characterization of the students, in order to verify if there was any improvement in their skills.

Data collection can be done thought questionnaires, interviews and surveys that together with record collection tools (from the Learning Management System we currently use) provide heterogeneous but integrated form of triangulating results. Statistical methods permit the final analyze of all data collected, which can give important contributions for subsequent courses.

Current work

We implemented this evaluation methodology in the Algorithms and Programming course (APRO). This discipline, with 4.5 credits – the highest possible, belongs to the first year of the Computer Science BSc. By completing this course, students are able to understand algorithmic concepts, analyze problems, develop and implement solutions.

This is considered a structural discipline. For this reason students must be successful before advancing to other programming courses. The school decided to allow failing students to repeat the course in the following semester, but with a different learning methodology: a mixed methodology with one weekly f2f practical session together with self-learning assignments and asynchronous online discussion. This methodology is also especially suited to a set of students, already employed, that have huge difficulties in combining their professional and social obligations and their school schedules.

In this study, our motivation was to test our evaluation methodology, verify its usability and determine if it could be used in other courses. We employed the five aspects selected in the first phase of the methodology:

1.**Contents quality** – In order to the APRO students use and interpret the available information, they had exercises to solve and sent by email until each Sunday every week; these exercises originated doubts that are answered by anyone. We used questionnaires to determine the quality of the contents (the contents were classified between 3 and 4 in a Likert scale from 1-very bad to 5-very good for all five contents' aspects argued) and also the number of mistakes detected (just two: one discovered by a student and the other detect by a teacher).

2.**Technological efficiency** – We evaluated the students' difficulties using the LMS that are supporting the APRO course and using other technological tools. Unfortunately, for some tools disposed to the students, 10% of them didn't use these tools, because they didn't know how to use them (for the more enthusiastic tools, no one said that).

3.**Communication effectiveness** – The number of email messages sent to teachers and messages sent to our discussion group by each student was used as a measure of this aspect.

4.**Students' satisfaction** –The number of APRO students that drop out the course compared with this rate from previous APRO courses will be used as a measure of their satisfaction. We also collected their opinions 2 times: in the middle of the course (68% of them were satisfied) and in the course closing (74% – we believe that the increase is because we carried out some of the suggestions given in the first inquiry).

5.**Students' success** – The learning outcomes of the students was measured in a similar way that was used in the past so we can compare the results at the end of this semester and can verify if there were great differences or not. Before the beginning of this semester we analyzed their previous examinations and completed an individual characterization of the students and we concluded that their main difficulties were the complex reasoning necessary to solve the problems proposed. All students that did the final examinations improved or kept (3 of them) their programming language (syntax and semantics abilities) and improved their previous grade from 1st semester.

We selected some context variables that could affect students' performance in a programming course: math background and previous programming experience (Wilson, 2001) and some others that we want to verify if they had any impact in the final results.

Data collecting (3rd phase evaluation) was done in a variety of forms: questionnaires, quizzes, interviews, surveys, pre and post tests, email registers and even in other more specifics way, some obtained thought the LMS (Learning Management System) that was used in the APRO course. This phase finished in the final of July, when the APRO students did their final examinations, so the data integration and the final data analyze (4th evaluation phase) is still being done. In the final database obtained, we have more than 50 variables.

Conclusions

Any evaluation has to identify problems, not only those that may become critical, but also discover the aspects that should just be improved in future courses. Only in this way it is possible to guarantee the continuous enhancement of the quality and efficiency of distributed learning courses.

In this paper, we discussed the importance of distributed learning evaluation and described an evaluation methodology that we think suitable for higher education courses. We present a study realized with 1st year Computer Science students, which permitted the improvement of our methodology, with later application in other initiatives.

Through an evaluation methodology, we intend that the evaluation can be done in a rigorous but fast way. The methodology being developed will be a guide to any course evaluation, with some adaptations, as the courses can differ in so many aspects. For example, eight hours seminary cannot be evaluated in the same way that a 120 hours course. Later, when this project is finished, we will study the automation of some of their evaluation phases.

How Can University Professors and Elementary School Teachers Work Together in Virtual Teams?

Mary Kay Bacallao
St. Thomas University
Miami, Florida
mbacalla@stu.edu

Aldo Bacallao
Lloyd Estates Elementary
Oakland Park, Florida
Aldobacallao@attbi.com

Abstract

A three-year virtual teaming project that connected professors from several universities with in-service teachers from diverse schools has led to some interesting discoveries about the nature of on-line work groups. These teams focused on the process of virtual teaming and produced an outstanding collaborative product for future use.

I. Overview of the Team Formation and Objectives

Across the state or across the street, people from different institutions with different roles and responsibilities came together on-line with a common purpose. In the first year of the project, their goal was to find out what works and what does not work in classroom technology integration. Eight distinct teams with subject matter focus posted weekly messages on a discussion board about attempts to integrate technology into teaching and learning.

The second year of the project built upon the foundation of the first year of trial and error in attempts to integrate technology into classroom instruction and relate to team members with different job responsibilities and philosophies of education. The team members had either achieved an acceptable comfort level or dropped out of the project. Some teams remained intact from the start of the project while other teams experienced a high dropout rate. The objectives for the second year were product based rather than process based, unlike the first year. The professors and pre-service teachers on the teams cooperatively wrote technology enhanced lesson plans according to the ISTE and Sunshine State Standards and published them on-line. The elementary teachers on the teams supplied the topic to be addressed and field-tested the lesson plans. The interaction between the team members took place via e-mail, posted discussion boards and chats. In some cases, the professors and the pre-service teachers made visits to the elementary school classrooms.

In the third year of the project, the teams will be multidisciplinary. Professors and pre-service teachers will be paired up with elementary teachers. They will cooperatively write multidisciplinary technology enhanced units according to the ISTE Technology Standards and the Sunshine State Standards. Although most of the work will still be accomplished on-line, there will be times for the paired groups to meet in person in the elementary teachers' classrooms.

II. Lessons Learned from Distance Virtual Teams

An analysis of the teams that were successful and the teams with high dropout rates were used to determine the qualities of team leadership that make for successful on-line work groups. Other factors such as the quality of the work produced were also taken into consideration. With attention to both the relational aspects of on-line learning and a focus on quality control from the team leadership, the components of an on-line environment for productive and comfortable on-line work groups will be discussed.

III. The Result of Cooperative On-Line Group Work: A Valuable Resource for Future Use

The ninety-six resulting technology enhanced lesson plans that are available on-line, written according to the ISTE Technology Standards and the Sunshine State Standards and field tested for Math, Science, Reading/Language Arts, ESE, ESOL, Curriculum and General Methods will be shown as resources for session participant use.

Multi-disciplinary E-Learning for Future Educators

Abstract

Where can professors find technology enhanced lesson plans for their college methods classes? St. Thomas University and Florida Gulf Coast University partnered with several elementary schools to connect pre-service teachers and professors with elementary school teachers. Eight subject-area teams met on line and then worked collaboratively to write technology enhanced lesson plans. Written based on the Sunshine State Standards and the ISTE Standards, the plans were housed on a database provided by a partner in Bay County, Florida, BEACON. (http://www.beaconlc.org) The lessons were field tested by the teachers at the partner elementary schools. The lesson plans are complete with the necessary assessment rubrics, web links, and/or associated files so that any teacher can download them for personal use. If you want to find many great technology lesson plans in one place, you can go to http://coe.fgcu.edu/pt3.

I. Virtual Teams are Formed

How can college professors make sure that they are preparing tomorrow's teachers to use technology in the elementary school setting? St. Thomas University and Florida Gulf Coast University partnered with several elementary schools to connect pre-service teachers and professors with elementary school teachers. In the first year of the project, subject area teams met on line to talk about attempts to integrate technology into teaching and learning.

II. Technology Enhanced Lesson Plans are Written to Address State and National Standards

In the second year of the project, the subject area teams worked collaboratively to write technology enhanced lesson plans. Written based on the Sunshine State Standards and the ISTE Standards, the plans were housed on a database provided by a partner in Bay County, Florida, BEACON. (Http://www.beaconlc.org) Once approved by BEACON for curriculum content and alignment with state standards, the lessons were field tested by the teachers at the partner elementary schools. The teachers provided feedback based on the field test to the professors and pre-service teachers. The lessons were then updated and put back on the web. The lesson plans are complete with the necessary assessment rubrics, web links, and/or associated files so that any teacher can download them for personal use. If you want to find all of these lesson plans in one place, you can go to **http://coe.fgcu.edu/pt3**.

III. Technology Experts Provide the Expert Review

On Saturday, June 8, 2002, technology experts from Miami-Dade and Broward Counties in South Florida met at St. Thomas University to participate in an expert review of the technology lessons created by the eight subject area teams. Their objective was to select the lessons that exemplified appropriate technology integration. The reviewers included: Rick Cunningham, Social Studies from ETS, Broward County Public Schools; Jose Enriquez, Exceptional Student Education, Assistant Principal, Palm Springs Middle School; Patricia Fritz, Reading Language Arts, 5th Grade Teacher, Tropical Elementary School; Shatril Harris, Science, START, Intel® Teach To the Future and Succeed Project Coordinator, Miami Museum of Science; Tanya Martin, ESOL, Human Resource Development, NOVA, Broward County Schools; Rose Parsons, General Methods, Senior Technology Specialist, Broward County Schools; and Dr. Pei-ru Wang, Curriculum, Educational Technology Professor, Union Institute and University.

IV. Lesson Plans Selected

The team of expert reviewers selected the following lesson plans:

Reading/Language Arts

Integrating Language Arts, Health, and Visual Arts by Dr. Antonio Fernandez (STU) and pre-service teachers Vinnie Vinciguerra and Zoyla Nodarse
View it by going to: http://www.beaconlc.org/boa/display.asp?lessonid=6413

Language Arts Through Web Page Research by Dr. Antonio Fernandez (STU) and pre-service teachers Vinnie Vinciguerra and Zoyla Nodarse
view by going to: http://www.beaconlc.org/boa/display.asp?lessonid=8331

All About Me Vinnie Vingena Vinciguerra
View it by going to: http://www.beaconlc.org/boa/display.asp?lessonid=6654

Social Studies

America's First Pictures by Dr. Frank Sicius View by going to: http://www.beaconlc.org/boa/display.asp?lessonid=9513

Disasters--Where, When and Why by Irving Kohn and Christina Chuderski
View it at: http://www.beaconlc.org/boa/display.asp?lessonid=9425

American Spy With Money to Spend by Joyce Honeychurch and Angela Greene
View it at: http://www.beaconlc.org/boa/display.asp?lessonid=9492

Alaska the Elephant by Dr. Joyce Honeychurch and pre-service teacher Angela Lavigne
View the lesson by going to: http://www.beaconlc.org/boa/display.asp?lessonid=8473

Are U.S. Presidents Leaders or Figureheads? By Irving Kohn View the lesson by going to: http://www.beaconlc.org/boa/display.asp?lessonid=8284

General Methods

How Much Do You Really Weigh? By Margaret Bogan and Linda Weber
View it at: http://www.beaconlc.org/boa/display.asp?lessonid=9359

English as a Second Language

Community Quilt by Dr. Manuel Bustamante
view it at: http://www.beaconlc.org/boa/display.asp?lessonid=8492

Science

The Many Phases of the Moon by Dr. Elizabeth Elliott and pre-service teachers S. Zamorski and L. Dwyer
view by going to: http://www.beaconlc.org/boa/display.asp?lessonid=8411

Exceptional Student Education

Guess What It Is? by Vicki McWhorter and Brenda Lazarus
view it at: http://www.beaconlc.org/boa/display.asp?lessonid=8486

Let's Go Fact Fishing by Tamre Church and Marci Greene
view by going to: http://www.beaconlc.org/boa/display.asp?lessonid=8428

Ocean Vocabulary Word Scramble by Tamre Church and Marci Greene
view by going to: http://www.beaconlc.org/boa/display.asp?lessonid=8421

V. What's Next?

The teams will now be re-arranged. They will be multi-disciplinary teams. Their next task will be to write technology enhanced mini-units for publication on the BEACON website. We can look forward to the completion of their work in December of 2002.

Essential Strategies for Connecting with the E-learner

Kathleen Bacer, Ed.D
Advanced Studies, Educational Technology
Azusa Pacific University
United States
kbacer@apu.edu

Abstract: This paper addresses essential strategies to effectively connect with the e-learner. The online learner enters the virtual classroom with a unique set of needs, expectations, and skills. Gaining access to those needs and expectations allows the online educator an opportunity to capitalize on strategies that effectively connect and create a dynamic e-learning experience. Strategies for communicating and connecting with the e-learner along with the utilization of a variety of online tools are delineated.

Introduction

Critical to any teaching/learning process is the ability to effectively connect with the learner enabling them to transform the instructional delivery system into a personal educational experience. While this is essential for any learning community, the online community poses a new set of challenges as the dynamics of the human interface are changed and facilitated by methods of telecommunication rather than the physical presence/interactions of students and teachers. As e-learning continues to sweep across the business and educational marketplace, many of the complexities of connecting with the learner continue to challenge us. Without the visual clues from the e-learner, the online educator must acquire a new set of communication skills to connect and implement sound instructional practices while translating them into an effective online teaching environment. It is an exciting and daunting challenge. The purpose of this paper is to provide strategies to equip the educator for connecting to the learner in an online environment!

Understanding the Online Learner and the Role of the Instructor

The online learner enters the virtual classroom with the same basic learning needs as the face-to-face (f2f) learner. They are usually on a quest to acquire new knowledge and skills, to validate who they may already be by obtaining a degree, and/or to be connected to colleagues for camaraderie and collaboration as they embark on their learning journey. Expectations may be another story. There may be expectations that they will have a lot more free time and/or the journey will be much easier by choosing the online paradigm. Coupled with those expectations also may be many apprehensions and fears that they will have problems with the technology and not be able to function online without the physical presence of an instructor to help when problems and questions arise. On the forefront though, the online learner is unique in that they value learning in their own time and space as more important than attending a physical classroom bound by time and space. While the connection to their immediate world is a high priority, they do still seek a sense of support and connection to their online learning community. Thus, the effective utilization of strategies to virtually connect with this learner becomes essential.

The online learner also has to acquire a unique set of skills independent of the familiar traditional learning environment. E-learning not only requires a higher level of responsibility and independence on behalf of the learner, but also an ability to attain proficiency in the utilization of technology to facilitate the learning. Perseverance and problem solving take on new dimensions in the e-learners' world.

Instructing e-learning provides an incredible opportunity to create a dynamic teaching and learning environment, if done properly. The online instructor's role is that of developing, delivering and creating a learning partnership within a community of learners. There are now many tools available to assist not only in the creation of online learning environments, but also for communicating the curriculum and connecting with the e-learner.

Strategies for Connecting with the E-learner

Connecting with the e-learner is at the core of effective online teaching. It is an art that requires an educator to effectively utilize the tools within the e-learning environment to deliver not only curriculum content, but to nurture, sustain, and challenge the e-learner in collaboration with the other e-learners.

1. Select an effective delivery system (e-learning environment)

Every e-learning environment has a delivery system whether it is as simple as a series of newsgroups, or as dynamic as a multi-dimensional learning portal. Although the purpose of this paper is not to focus on the many types of delivery systems currently available, an essential strategy for consideration when analyzing your goals and objectives and student outcomes for the online learning environment is what features and tools the delivery system offers for

BEST COPY AVAILABLE

communication and collaboration. I currently utilize ecollege http://www.ecollege.com and TappedIn http://www.tappedin.org for the delivery of a Master of Art in Educational Technology program.

Things to consider when selecting a delivery system:

- Is it relatively easy to set up, edit, utilize?
- Whose server does the curriculum content reside on? Is it stable?
- What tech support services are available for the student and instructor?
- What collaborative tools are available for asynchronous and synchronous discussions?
- Is the interface transparent or is transparency easy to master? In other words, it is user-friendly and intuitive so that the interface doesn't hinder the learning? After one session, will students no longer think about the delivery system, but focus on the curriculum?

2. Utilize the delivery system's interface to effectively communicate/present the curriculum.

For e-learning, how you utilize the capabilities of the interface becomes your vehicle for communicating the content of the course. This involves first and foremost the use of instructional design elements in a manner that we as educators have never been asked to implement before. We so often depend on the "lecture" modality in higher education. A modality I have always scrutinized in relation to an effective teaching/learning strategy/environment. Moving instruction online actually forces us out of the lecture mode and into the interactive mode. A much more effective teaching pedagogy! Thus, I consider the instructional design of the curriculum within the interface the most critical element. It is where the learning actually revolves, where the e-learner formulates many first impressions, and often decides what kind of a learner they want to be in the environment. For a f2f classroom, a physical classroom/building and the physical interactions with colleagues and instructors may determine these learning factors. The interface that the course is encased in and the manner in which the content is delivered becomes the external environment of the virtual classroom. Ask yourself:

- What will you do to promote inquiry and learner-construction of the knowledge instead of reading pages of text driven online materials?
- How will you design an instructional environment that stimulates and encourages the learner to take the learning to the next level?
- How will you engage the learner without your physical presence?

In delivering online curriculum, tapping into and utilizing the wealth of resources available in the e-world are essential. I cringe when I see instructors scan pages of lecture notes, post what I call "scroll down marathons", videotape whole lectures, and post pages of text driven information. Resist the temptation to take your current teaching strategies in the f2f classroom and try to transfer them online unless they are dynamic and interactive!

Things to consider in designing and delivering the curriculum:

- Are you utilizing a variety of ways to present the information such as visually stimulating presentations with graphics, colors, bulleted lists, graphs, audio and video clips, interactive pdfs (portable document format), web resources, etc…?
- Does your content have built in student accountability? In other words, is there a communication system that allows the learner to interact and respond to the content thus demonstrating learning and continued construction of knowledge?
- Is the content in sizeable learning chunks? Since elearning is no longer bound by time and space, content needs to be "resized" so to speak to maximize flexibility and empowerment for the learner. Believe it or not, brevity utilized online actually reinforces attentiveness.

3. Invest in the Learner – Connect, Communicate, and Collaborate

This is obviously the heart and soul of any effective teaching pedagogy. The online environment is no different, and in many ways requires a much different time and instructional commitment on the part of the instructor. In the online environment, since visual cues are almost non-existent and gaining a sense of teacher/learner presence is more challenging, investing in the learner with effective ways of communicating and developing a sense of community become essential and foundational. E-learning does provide many unique opportunities to effectively connect, communicate, and invest in the e-learner. It is important to note that the online environment you create needs to include a high level of collaboration not only with you as an instructor but fellow colleagues otherwise you will have for example, twenty isolate e-learners. Although at times it may appear to be a 24/7 task, it is well worth the learning outcomes. Out of an effective virtual classroom, the learner may experience a depth that is sometimes not obtainable in a f2f environment. E-learners cannot "hide" behind other learners, e-learners have much more time to reflect on their "verbal" contributions, and e-learners have access to a non-threatening, virtually risk-free learning environment in which the hierarchal levels of instruction become an equal communication field. Within this arena are many different interactive communication/connection tools that can be successfully utilized. For clarification, communication tools can be categorized into two groups – synchronous and asynchronous. Tools that facilitate synchronous communications allow the participants to communicate at the same time within a common virtual space. Tools that facilitate asynchronous communications may share the same space (as in threaded discussions), but the e-learners are working and collaborating at different times. Note that space is virtual, not physical.

BEST COPY AVAILABLE

Outlined below are some of the most common and effective communication tools available to the e-learner and online educator along with utilization strategies.

Synchronous communication tools

- Telephone

Many forget this simple and effective communication tool in the online environment. I find it essential to connect with each of my students via phone in the beginning so we can "hear" each other's voices and establish a connection with a familiar modality. Since the online environment is sometimes initially invisible to the learner, a simple phone call is very helpful in getting them started. I also encourage the students to have phone numbers of several other colleagues for those times when all else fails.

- Virtual classrooms

Many delivery systems are now including a "chat" area where synchronous conversations and collaborative work can take place. This is a great way to virtually meet and work with students. Within them, many have white boards and capabilities of recording the conversations. Obviously time zones need to be taken into consideration for all synchronous class sessions. My personal favorite is Tappedin – http://www.Tappedin.org. This is a dynamic professional educational environment linked to a whole community of educators and teaching resources. Although there is a little bit of a learning curve to be able to function within the environment, there are powerful teaching tools within to enhance synchronous online instruction.

- Instant Messaging

Much like the telephone, instant messaging actually provides a unique mode of connection to the learner/s. I create "buddy lists" for each of my classes so that students, when online can have a sense of connection to not only the instructor, but to each other for support and collaboration. Suddenly the sense of aloneness and isolation that can easily occur in the online learning experience disappears! The nice feature with Instant Messaging is that you can choose when you want to be available/visible to others and when you don't want to be disturbed.

Asynchronous communication tools:

- Snail mail

While one may question if this even has a place in e-learning, I have found it a refreshing tool for the learner encased in an online environment. Sending a written note of encouragement or even a small "care" package at some point during the class is a powerful connection tool!

- Email

Usually everything in an online class revolves around this basic communication tool. It is what I refer to as the first layer of a class, commonly known as "push" technology. You don't have to go through layers to retrieve it. It's right there in your face, so to speak. The key to effectively utilizing email is an efficient organization, management and possibly a filtering structure if you deal with a high volume of email. It is well worth the time and effort to educate your students on the use of effective subject headers that include their name and assignment, and an email management system. A good delivery system has a communication center within that facilitates the ease of individual and group emails.

- Threaded discussions

Acting as the hub of classroom issues, learning and conversations, threaded discussions allow for adequate reflection and interactive discussions. Author editing and being able to view all conversations/threads at the same time should be a part of this interface. While this can be an important forum for teacher/student interaction, it also can be utilized to keep the learner on task, move the learning to the next dimension, and allow the learning community to construct knowledge in new and meaningful ways. The key is to teach students how to include parts of previous conversations so that the discussions are held together and the flow is maintained.

- E-Journals

Some delivery systems have a method within the interface in which students and the instructor can interact privately. Much like what can be done in email, e-journals provide an environment within the virtual classroom for one-on-one personal reflection and interaction with the instructor. They are private and I have found them to be an excellent tool in establishing an effective relationship while gaining valuable insight into individual learning and perspectives. A dynamic e-learning experience allows both instructor and student a new sense of shared space.

- Data collection resources (known as a webliography in ecollege)

This is a place where students and instructors can share online resources they feel are important to the learning objectives. Utilizing a space in the online environment for resource sharing allows for the next level of resource sharing and networking.

- Document sharing

This is all part of collaborating, reflecting and learning from each other's work. While this should be a dimension of online learning, an important factor to consider is how you would like your students to share their documents whether it be as word documents, portable document format (pdf), PowerPoint presentations, web sites, or all of the above. If your delivery system has a document sharing area, it greatly facilitates this form of communication versus having students send their work as attachments to emails. Student work becomes an expression for all to benefit from when appropriate.

- Online gradebooks

In the online environment, I find it most effective to provide feedback weekly. Initially some of the work may not be as visible and expectations are new, thus providing weekly feedback is an essential part of the communication process.

Other helpful strategies

- Timelines

One of the common challenges in the online environment for the e-learner is time management. Since there is a newfound flexibility, many times what I refer to as "out of sight, out of mind" syndrome takes over. I have found it most effective to divide the modules (sessions, weeks, workshops) into time frames in which the modules are "time released." While I have tried many different strategies, the most effective has been to open the sessions on Friday so students can use weekend time to get ahead, and then close on the next Friday (if working with a weekly timeframe). It is also very beneficial to set participation criteria in the online classroom so that there is adequate collaboration and construction of learning. For example, require students to post at least 4 different days within a week. Postings need to add significantly to the discussions for credit.

- Useful Software

While a good word processing software is essential for online work, Adobe Acrobat is also a powerful tool for sharing work as portable document files (pdf) preserving the fonts, graphics and look the author intended for their work. It is also beneficial to invest in utilities such as StuffIt Deluxe (for Mac) and WinZip (for PC).

- Class size

The ideal manageable online class size for both instructors and learners, I have found is actually twelve. Take into consideration the increased level of interaction, responses and collaboration that occur within the virtual classroom – much higher than a f2f classroom. To adequately service each learner and also provide him or her with a manageable environment, class size is a much-debated issue. There are many misconceptions that it is much less time consuming to teach online – simply not so if done effectively and dynamically.

While these are some of the most common communication and collaboration tools, there are others that may prove useful. It is important to focus on the effective utilization and implementation of any online tool to break down the barrier between the instructor and student, to create a dynamic learning community and to enrich and celebrate the accomplishment of connecting and empowering the learner. One of the unique benefits of connecting with the e-learner in an online environment is the equal playing field that emerges. By this I mean the hierarchy between instructor and student disappears online. Students whether synchronously or asynchronously have an equal voice and chance to participate, learn and grow. While it is sometimes a timely investment, your presence and being available is extremely important to the success of any online environment. Make that online presence positive, supportive, and creatively visible!

Evaluation of a Web-based Tutorial on the History of Technology in a University Science-Technology-Society Course

Patricia Ryaby Backer
Department of Aviation & Technology
San Jose State University
San Jose, CA USA
pabacker@email.sjsu.edu

Abstract: This paper will discuss the development and evaluation of this new unit on the history of technology. The web-based tutorial was evaluated both by content experts as well as through a student-driven assessment model. Although this web-based unit was developed by the course coordinator, four other faculty regularly taught this course and all faculty teaching this course use both the multimedia CDs as well as this web-based unit. It was critical to the success of this web-based unit that all faculty could feel secure in using this web-based unit in their classes.

Introduction

In university settings, the field of technology education has been expanded in the last ten years with courses that focus on the interactions of technology and society. These courses are presented in various ways; some focus on the ethics of technology while others take an artifact-based approach. In many cases, however, these courses expand the traditional field of technology studies to a greater student population through either General Education or as required courses in other disciplines. In broadest terms, these courses can be classified as science, technology, and society (STS) courses.

The Department of Aviation and Technology at San Jose State University (SJSU) has offered a STS course under the university's General Education (GE) curriculum since 1981. This course, *Technology and Civilization*, has been housed in three different General Education areas. It began as a course in the Social Sciences area and was categorized under Social Issues. In 1992, SJSU dramatically revamped their GE program. GE was divided into lower division GE, which a student could complete a local community college or at SJSU, and upper division GE, which had to be completed at SJSU. All the classes in the upper division GE had to be interdisciplinary and include an extensive writing requirement. *Technology and Civilization* was granted advanced GE status as a course in two Areas: Earth and the Environment and Cultural Pluralism.

SJSU revised the GE program again in 1998; this revision required that the university's Board of General Studies certify all courses. The focus was put on designing the courses to ensure that the students met the student learning objectives for the GE area. The general education program at San José State University (SJSU, 1998) is different from many in the United States. Instead of specifying a specific series of courses as part of the General Education (GE) of each student, SJSU has five Core GE areas (Skills, Science, Humanities & Arts, Social Sciences, and Human Understanding and Development). In addition, every SJSU student must take Advanced GE courses in four areas: Earth & Environment; Self, Society & Equality in the U.S.; Culture, Civilization & Global Understanding; and Written Communication. Any department may propose a course for any area of GE. Beginning in Fall 2000, *Technology & Civilization* (Tech 198) was approved in the Advanced GE Area V, Culture, Civilization & Global Understanding where it remains an approved course today. The department decided to move it from Earth & the Environment to Culture, Civilization & Global Understanding because the course no longer fit within the revised goals and student learning objectives of its original GE area.

The structure of this course

Tech 198, prior to its certification as an advanced GE course in 2000, already used a variety of multimedia to deliver the content. The approved Fall 2000 version of this course had seven units: **The Nature of Science and Technology, The History of Technology, Technology and Work, Technology and Gender Issues, Technology**

BEST COPY AVAILABLE

Transfer, **Quality of Life Issues**, and **Ethics**. Previously, Backer (1996, 2000) had developed two of these units as self-paced multimedia units that currently are being used by all instructors in this class. In order to meet the area goals and student learning objectives of SJSU's GE area V, the department decided to add a new unit on the history of technology.

This web-based unit on the history of technology was part of a reconceptualization of this course as a hybrid (self-paced multimedia/Web/in-class) delivery model. When completed, four of the units would be delivered through self-paced multimedia CDs (**The Nature of Science and Technology**, **Technology and Work**, **Technology and Gender Issues**, and **Technology Transfer**) one would be a web-based unit (**The History of Technology**), and two (**Quality of Life Issues** and **Ethics**) would be delivered in a traditional classroom mode. The department faculty had committed to retaining the two in-class units so as to provide more active learning and open-ended inquiry for the students. In addition, the faculty believed that the two in-class units would best be taught using a traditional, face-to-face classroom environment. The key issue for all the self-paced modules was their effectiveness in promoting student achievement of the course's learning objectives.

The introduction of a new unit on the history of technology enhanced the content of this course in many ways. First, this unit addressed the contributions made by people of different cultural groups. Second, this unit, since it was positioned between the existing Unit 1 (**The Nature of Science and Technology**) and Unit 2 (**Technology and Work**), provides a stronger historical context to this course and subsequent discussions of technology and society. The History of Technology web-based tutorial is divided into three major sections: Technology in the Middle Ages, Chinese Contributions to Technology, and Islam Spain and the History of Technology. This web tutorial is available at two different sites: http://www.engr.sjsu.edu/pabacker/history/ OR http://www.mastep.sjsu.edu/history_of_tech/.

In order to retain certification as an Advanced General Education course at SJSU, all sections on this course had to meet the learning objectives for Area V (Fig. 1). Therefore, the effectiveness of this unit in meeting the goals of GE at SJSU is critical in evaluating its content. In fact, since this course has to retain GE certification to continue in General Education, one could argue that the achievement of the GE learning goals for Area V are the most important measure of student success in this class. This shift in focus, from a content-driven to student-achievement model, led the development and assessment of this web-based unit.

1. Goals

Courses in Culture, Civilization, and Global Understanding should give students an appreciation for human expression in different cultures and an understanding of how that expression has developed over time in different cultures. These courses should also increase students' understanding of how other cultural traditions have influenced American culture and society, as well as how cultures in general both develop distinctive features and interact with other cultures.

2. Student Learning

Students shall be able to:

- compare systematically the ideas, values, images, cultural artifacts, economic structures, technological developments, or attitudes of people from different societies;
- identify the historical context of ideas and cultural practices and their dynamic relations to other historical contexts; and
- explain how a culture changes in response to internal and external pressures.

Figure 1. Area Goals and Learning Objectives for Area V of SJSU's General Education. Available: http://www.sjsu.edu/ugs/ge/geguidelines.html

The Study

There are two parts of the assessment of this unit. First, there is the content assessment. The content of this unit has been evaluated by faculty from various departments at SJSU including faculty in industrial technology, history, and engineering. A section on Muslim contributions to science and technology was added based on the feedback from content experts and a review by student focus groups. The second part of the assessment is centered on the efficacy of this unit as a learning modality for students.

The web-based unit on the history of technology was first used in Fall 2000 in all three sections of this course, which were taught by three different instructors. Since then, they have been used continually in all sections of the class each semester. This has allowed the faculty to complete a long-term assessment of the effectiveness of this module. As discussed previously, this course is structured to measure assessment by student achievement of the learning goals for Area V of SJSU's GE program. At the end of each semester, every instructor submits an assessment report to the course coordinator that describes how the student learning goals were measured and how many students met each learning goal. Each instructor may use various, and usually multiple, measures of student performance. Overall, in the thirteen sections offered between Fall 2000 and Winter 2002, eighty-four percent of the students (266 out of 316 students) demonstrated that they achieved Area V student learning objective 2. Although this web-based unit was focused on this specific student learning objective, the instructors of this class generally used multiple measures of student learning. Five individual sections were analyzed in detail to determine the effectiveness of this web-based unit alone in assisting the students to meet Area V learning objective 2.

This detailed analysis of the five sections (Tab. 1) showed that the history of technology web-based unit was very effective in helping student achieve Area V student learning goal 2. Most of the students in five sections of the class (71 %) demonstrated their achievement of understanding "the historical context of ideas and cultural practices and their dynamic relations to other historical contexts" by their responses to the class activities at the end of this web-based unit. Ideally, all the students should be able to demonstrate they met all the student learning goals; however, not all students are motivated to excel in all of their classes. Considering the number of different instructors teaching this course, the results confirm that this web-based unit is effective in helping students to demonstrate their understanding of this student learning objective.

Semester	**Total Number of Students in Each Section**	**Students meeting learning objective 2 using all measures**	**Students meeting learning objective 2 through Unit 2 class activity**
Fall 2000	23	22	22
Winter 2001	26	23	21
Spring 2001	31	27	20
Summer 2001	24	22	12
Winter 2002	26	20	17
Total	**130**	**114 (88 %)**	**92 (71 %)**

Table 1. A detailed analysis of the effectiveness of the web-based learning unit in assisting students to meet Area V learning objective 2, "identify the historical context of ideas and cultural practices and their dynamic relations to other historical contexts"

Conclusions

Over the last several years, the use of the Internet has burgeoned. The World Lecture Hall (2002) at the University of Texas indexes web-based courses—it lists hundreds of web-based courses that cover a wide spectrum of Internet use in the college classroom including eight that are in STS studies. It is common to find instructors creating a course web page that has links to their syllabus, lectures, and web links related to their course; these courses are classified by Schmidt (2002) as web-enhanced classrooms. Other courses are offered totally in an online environment and might include text, video, or audio lectures or seminar discussions through email and listservs (Bazillion & Braun 1998).

As the use of the Internet explodes, there has been little emphasis placed on the effectiveness of these web-based classes in facilitating student learning (Ehrmann 1997). A seminal study (Russell 1999) analyzed over three hundred articles that evaluated multimedia and web-based materials and found that overall there was little difference between technologically-enhanced courses and traditional lecture courses. Efficiency is also a concern with web-based delivery systems. Many studies (Harapnuik, Montgomerie, & Torgerson 1998; Morgan 2000; Hecht & Schoon 1998) have noted the extensive time involved in developing web materials. Now, in addition to being a content expert, the average faculty member must become a web designer. The question is: Why use web-based instruction in a course?

Web-based instruction in industrial technology programs, like any other area of expertise, should only be used when it can add value to a course. The self-paced multimedia and web-based modules developed for this course fulfill this expectation. The web-based history of technology unit provided links to digitized primary sources and integrated technological development with history. More importantly, it allowed the sharing of expertise among the faculty. The faculty teaching this course were able to utilize the expertise of the course coordinator who developed this web-based unit. Since this course is taught by many different faculty, it allowed them to individually focus on selected topics in more detail after the students had completed reading the web-based material. The links to primary sources also are critical to expanding the students' world views. Also, this unit requires students and instructors to expand their perceptions about technology. Including the two sections on non-Western contributions to technology have lead the students to an increased understanding of the complexities of both technological development and history itself. Each semester, several students comment as to how this unit really "opened their eyes" to either Chinese or Muslim contributions to technology.

Although some would argue that there is a lack of studies on the general effectiveness of university instruction, the existing teaching model has persevered for a long time. Now, when confronted with a new model of instruction—web-based learning—faculty need to re-evaluate the measures they use to evaluate the effectiveness of the learning experience. The student-centered model presented here focuses on student achievement rather than faculty expertise. Although used here to evaluate web-based instruction, class evaluation using student achievement of learning objectives can be applied to any teaching modality. For technology-based courses, what students learn should be more important than what instructors teach.

Abstract: The aim of this paper is to develop a perspective on the use of computers for teaching and learning in higher education that can help us to devise strategies for research and development. In so doing, the paper examines current computer applications in order to gain a better sense of the ways in which computers have become a part of teaching and learning in higher education, and the ways in which these uses are limited. The focus is on the mainstay of instructional technology, course management systems, and Blackboard as a prime example of such software. The paper contends that now that course management systems have become the primary platform for the distribution of computer-based instruction in higher education, it is time to develop more fully the instruction these systems deliver.

Introduction

The aim of this paper is to develop a perspective on the use of computers for teaching and learning in higher education that can help us to devise strategies for research and development. In so doing, the paper examines current computer applications in order to gain a better sense of the ways in which computers have become a part of teaching and learning in higher education, and the ways in which these uses are limited. The focus is on the mainstay of instructional technology, course management systems, and Blackboard as a prime example of such software. The intent is to foreground not only what Blackboard and other such systems actually do, but also what they do not do, and thus to shed some light on areas that need to be addressed in the future.

Blackboard in Context

There are, of course, any number of ways of viewing instructional technology. For present purposes, functionality is of primary importance since we are concerned with the uses of technology. From this perspective, we can identify three distinct classes of software used in higher education: productivity and communications software, stand-alone instructional courseware, and course management systems. Let us look at each in turn.

Productivity and Communication Software

We rarely think of productivity and communication software as instructional in nature. And yet such software is, without doubt, the most frequently used in higher education for teaching and learning. Faculty create syllabi and other course documents with word processing software, while few students would even dream of writing their assignments without it. Spreadsheets are used by professors to enter grades and frequently by students as a software aid for calculating and organizing data. Email software has made it easier for students and faculty to communicate with each other and among themselves, as well as providing a new way of sending and receiving student assignments. The World Wide Web and the graphical browsing software we use to access it have allowed both students and faculty to gain access to volumes of material that would not otherwise be available.

How ubiquitous is the use of productivity and communications applications? As anyone in higher education in the United States knows, word-processed student written assignments are the rule, while the Web has become a primary means for students to obtain research information (OCLC White Paper, 2002,

p. 8). The use far outweighs computer applications that are more specifically focused on education. Consider the fact that according to the Campus Computing Project in 2001 only 35.2% of courses have a course Web page, and that the number of courses that use course management systems is under 30% for both four-year institutions and community colleges (The Campus Computing Project, 2001). When we think of the role of computers in education, it is important to keep in mind that the most frequently used applications in the teaching and learning process are not those specifically intended for education.

Stand-Alone Instructional Courseware

Stand-Alone courseware comes in many different varieties. For present purposes, we will briefly touch on four types: page turners, quizzes, games and simulations. Page turners, or tutorials as they are frequently called, allow students to access materials from a computer monitor. These page turners may be nothing more than one or more web pages (see, for example, FindTutorials.com). Quizzes and tests come in a variety of formats, just as they do in Blackboard, and there are a wide variety of feedback and scoring mechanisms (see, for example, Darling, 2002). Simulations allow students to see what happens, for example, to investments or to the well-being of a city, given alternative sets of facts, (see *alphaWorks*, 2001). In instructional games, targeted knowledge or skills are required for success; for example, a virtual tour of France in which the student can only get from one point to another by using the correct French terms.

Colleges and universities then have a variety of choices for creating stand-alone programs. Not only is stand-alone software offered in prepackaged forms; templates and authoring software are also available. The courseware creation software can range from generalist products such as Macromedia's Authorware to the programs that focus on creating specific kinds of software for a specific kind of domain. There is a wide range of software, and the issue is not so much finding software, but rather deciding on the particular strategy that is appropriate in a particular educational context.

Course Management Systems

Course management systems are a force to be reckoned with. Nearly three-fourths (73.2%) of the institutions participating in the *2001 Campus Computing Survey* have selected a single course management system for use in courses. This figure indicates a dramatic increase from 57.8% over the previous year (The Campus Computing Project, 2001). If nothing else, the numbers suggest increasing institutional resolve to encourage the use of course management systems in postsecondary education. For this reason, if no other, it is important to look carefully at what course management systems offer to assess their role in teaching and learning in higher education.

Two of the largest providers of course management systems are Blackboard and WebCT. Although they differ in a number of respects, their basic functionalities remain the same (Sabine, 2001), and discussion of functionality can be restricted to Blackboard in order to simplify discussion without any substantial loss of generality.

Blackboard may be considered to have three basic sets of functions: (1) features that allow the teacher to present content of one sort or another, (2) features that allow the teacher and students to communicate with each other, and (3) features that allow the teacher to assess in one manner or another. All three offer functionalities that exist elsewhere, a point that becomes quite evident from even a cursory examination. Let us look briefly at each in turn.

In Blackboard, there are three basic mechanisms for delivering content: (1) adding it directly to a page, (2) attaching files, and (3) adding links to other material. The first of these is rather straightforward. You simply type or paste in text, or using Blackboard procedures, you insert a graphic. Attaching content is really nothing more than the process we use when we attach email files. The file—be it a text or image file or some form of multimedia—is made available by uploading it to Blackboard. Links are created by specifying the address of the file; the student then simply clicks on the link to access the material.

Communications in Blackboard has four basic components: email, Discussion Board, the Drop Box and the Virtual Classroom. Unlike WebCT, Blackboard uses external email accounts, but in either case the basic functionality is the same. The Discussion Board is a posting board where students and faculty can post and respond to messages, while the Drop Box provides a way for faculty and students to send files back and forth to each other. The Virtual Classroom combines chat with a whiteboard through which slides can be presented to students.

Assessment in Blackboard comprises quizzes and surveys. Both use the same basic question forms: multiple choice, fill-in-the-blank, item ordering, true-and-false, item matching, multiple answer, and short answer/essay forms. The assessment component of Blackboard also offers a record-keeping facility, and the results from all assessments except short answer/essay types are marked automatically. Still, there is a difference between surveys and quizzes: answers to surveys are anonymous, while the results of quizzes are not. As well, teachers can use the record keeping facility as a kind of basic spreadsheet in which they can enter marks from other assessments that are not part of Blackboard.

The Role of Blackboard in Teaching and Learning

If we step back and examine Blackboard's capabilities, we are struck by one basic fact: all of Blackboard's basic functionalities are available elsewhere. Consider what it offers by way of delivering content: the ability to attach (upload) files, link to other addresses, or paste and type in content. Anyone with basic Web skills can do the same without Blackboard.

The communication functionalities are also available elsewhere, as we can see by looking at each Blackboard communication component in turn. Blackboard's takes advantage of external email accounts, but even if it followed WebCT and offered its own, the basic functionality would be the same. The Discussion Board takes essentially the same form as the Internet News Groups and the many discussion boards that are ubiquitous on the Web. The Virtual Classroom is basically a combination of chat and whiteboard functions—both of which are easily available elsewhere.

Just as the functionality of Blackboard's communications features mimic the functionalities of general communications software, so do the functionalities of the assessment component mimic the functionalities of basic testing software. The basic assessment quiz types can all be created even by a general authoring system such as Authorware. Moreover, there is a wide range of materials available as stand-alone packages, and templates and authoring systems offer far more strategies and options than does Blackboard.

What is it then that course management systems offer that cannot be found in either productivity and communications software or stand-alone courseware packages? What accounts for the fact that between just 2000 and 2001 the number of postsecondary institutions participating in the Campus Computing Survey selecting a single course management system has risen from 57.8% to 73.4% (The Campus Computing Project, 2001)?

The answer, at least in part, is quite simple: distribution. Course management systems offer a standardized means of delivering content, communications and assessment. The key point is not just that they allow a standardized way of distribution, but that they offer a way of controlling the distribution. Course management systems offer a way to deliver instruction to those who are supposed to receive it, and a means of keeping out those who are not. This gate keeping function is basic to the integrity and survival of postsecondary institutions, and neither communications packages nor stand-alone courseware offer institutions anything similar, while at the same time providing a diverse array of teaching and learning functionalities.

Beyond Blackboard

The large and increasing number of institutions selecting a single course management product would suggest that such systems are becoming the basic standard for offering computer-based instruction at the postsecondary level. Nevertheless, course management systems, for the most part, employ little of the computer's potential as an instructional tool.

It is true that publishing companies are beginning to supply course materials to accompany the texts they sell, and some of these materials can be offered easily through course management systems. Still, the potential for instruction delivered through these systems has barely been tapped

A modest step towards harnessing the potential might be to find ways to deliver through course management systems at least some of the wide array of stand-alone programs that offer at times more sophisticated learning technologies than the course management systems themselves offer. This, however, would be only a first step. Much more is possible.

Consider the fact that our ability to track online behaviors can allow us to identify areas of student interest to a degree that neither teachers nor librarians could ever hope to achieve without technology. This ability is already being used commercially by Amazon and other retailers. Educators could well use the same technology to push automatically links to articles and other types of educational content, based on a tracking of online articles a student has accessed from a course management system.

Consider also the potential of the computer to individualize instruction. One of the things that computers force us to do is to represent knowledge in terms of interrelated but logically discrete units. The knowledge that goes into making a simple arithmetic computation, for example, may be represented in terms of a series of discrete, logical steps. These representations can allow us to identify in a clear manner what students know or don't know—at least as it can be inferred from their performance on some task or set of tasks. In fact because of the logistic nature of computational representations, we can make precise identifications of areas in ways in which no human teacher could even under the most optimal of circumstances. This, in turn, can allow us to adjust instruction to fit what a student needs (see Wenger, 1987). The area is still relatively new, but research and development in the field (see *Intelligent tutoring systems*, 2000-2002) offers the very real possibility of using instructional technology to individualize the teaching process itself in ways that might not be otherwise possible.

These are only two ways in which course management systems could be harnessed to offer more individualized teaching and learning; many others are no doubt equally worthy of attention. The potential is there. Now that the course management system has taken hold as the basic distribution paradigm, we can begin to investigate more thoroughly such ideas, ideas that relate directly to the actual instruction we want the systems to deliver.

Abstract: Appalachian State University, in conjunction with the North Carolina Consortium for Distance Education In Communication Sciences and Disorders, makes it possible for public school Speech-Language Pathologists to upgrade their credentials by obtaining a masters degree. Naturalistic inquiry was used to identify factors important to surviving and succeeding in ASU's distance education program. Specific procedures used in this investigation included (1) initial interview, (2) data analysis, and (3) subsequent interview (emergent design). Participating subjects unanimously and independently identified the following factors as the most important determinants of success in this program: (1) immediate and extended family support, (2) advisory assistance, (3) career motivation, (4) persistence, (5) camaraderie with other students, and (6) development of technology skills. Advisory assistance and student support mechanisms provided by the program structure are described.

Introduction

Appalachian State University (ASU) students pursuing a masters degree through the North Carolina Consortium for Distance Education in Communication Sciences and Disorders (CSD) have performed very well (Barber, 2002). They have been successful in distance coursework even when enrolled in two distance education courses while maintaining full time employment as public school Speech-Language Pathologists (SLP), despite low admissions formula scores. They have accomplished this feat while living and working in their pre-enrollment environment, so they have had to make dramatic changes in their personal time habits.

Most of the students participating in the Consortium masters program in CSD through ASU have been unable to attend classes during the traditional public school year, even at interactive sites. Therefore, most have viewed classes via videotapes. Other than a one time a year retreat, their communication with other students has been almost entirely via email or telephone. They also have very limited face-to-face interaction opportunities with course instructors. Almost all of the distance courses of the Consortium program rely heavily on technology, including web pages, threaded discussions, and chat rooms.

Consortium students take distance courses while working as public school SLPs during the school year, but they are usually on campus for summer coursework. ASU distance students take on-campus summer courses during eight-week sessions in each of at least two summers, and they complete a supervised clinical practicum each of those two on-campus summers. These summer experiences afford the opportunity for students to develop working friendships with each other that undoubtedly enhance their distance interactions during the traditional public school year.

Student Support Mechanisms

The Consortium provides support for the CSD distance education students through four mechanisms. Personnel who provide support include a Consortium Coordinator, and five Campus Coordinators. Support to facilitate communication and network building is provided by scheduling a pre-admission orientation and a yearly fall retreat for the students in this program.

A Consortium Coordinator answers telephone inquiries and maintains a list-serve and Consortium web page through which general information on course offerings, interactive sites, videotape distribution, course texts, course web pages, and related matters are disseminated to Consortium students. Students contact the Consortium Coordinator when they have questions about textbooks or course delivery mechanisms, when there are problems with videotape delivery or quality, when they have issues with instructors or campus coordinators, when they experience conflicts between their public school jobs and their distance education course workload, or when they have personal problems.

There is a Campus Coordinator at ASU and at each of the other Consortium universities; the Campus Coordinator serves as an academic advisor, technology information resource, distance-education student advocate, trouble-shooter and primary contact for the students enrolled through that campus. The Campus Coordinator is a faculty member with other duties, but with some reassigned time for serving in the campus coordinator capacity. Students contact the Campus Coordinator when they have scheduling or enrollment problems, financial aid issues, or technology issues, or when they need help navigating the bureaucracy of university administration. The Campus Coordinator is also frequently contacted about conflicts between student's public school jobs and their distance education course workload, or when students have personal problems, so these functions are shared with the Consortium Coordinator.

The Consortium conducts an orientation for all incoming students prior to their first summer of enrollment. This orientation lasts about six hours, and includes an introduction to the structure of the Consortium, delivery modes for distance education courses, library access, and technologies to be utilized in dstance coursework. The orientation provides the opportunity for review and discuss home computer needs and requirements, to insure that all incoming distance students are fully aware of their technology needs. Orientation also provides the first opportunity for distance education students to meet other new students enrolling through the same university, as well as students enrolling at other Consortium universities who will be their fellow students in their distance courses.

Early in each fall semester, the Consortium holds a Friday evening and all-day Saturday retreat to bring together students from all five Consortium universities. Attendance at these retreats has been close to 100% every year. The overnight stay is characterized by a lot of bonding of students who had previously known each other mostly via email, and who have much in common since all are, or recently were, working as public school SLPs. Instructors of current and future distance courses attend the retreat, so students get to talk with their instructors face to face. The retreat serves as a forum for airing concerns and problems, and provides valuable feedback to the instructors. There are also more general discussions about Consortium plans and the addressing of issues that arise when students try to balance their roles as students and public school SLPs with their roles as parents, wives or girlfriends. After the first student cohort graduated, Consortium graduates were invited to attend these retreats to share with current students the problems they had encountered as distance education students and solutions that worked for them. On more than one occasion, open forum statements by Consortium graduates, and sometimes by students nearing graduation, have turned into pep talks, or into testimonials praising this distance masters program.

Statement of Problem

Gordon (2000) identified three factors that he said were inevitably lost in on-line education. In addition to the obvious factor of "campus life", he listed "full communication" and "empathy and courage of commitment" as being lost. The students in this program do have the opportunity to stand up for what they believe during their on-campus summer experiences, in their off-campus clinical practica, during a full-time internship experience, and at retreats. Students viewing videotapes or attending interactive classes can pick up the instructor's non-verbal cues. Still, the reduction in opportunities to communicate with the instructor and other students might be expected to have an undesirable impact on the educational environment. Yet, ASU students have been very successful in this program and the program has retained or graduated sixteen of the eighteen students who enrolled in the ASU distance education program. In fact, only one of the those eighteen students did not continue graduate work in CSD; the other student who left the ASU distance program became ineligible when she chose to move back to her home state of New York, where she enrolled in an on-campus graduate program in CSD.

Both the low attrition rate, and the high scholastic performance, of the ASU distance students in this program are contrary to many experiences with distance education that have been reported in the literature (Gordon, 2000). We wanted to investigate how students in this program were able to succeed in distance education under these circumstances. In order to allow the course of this investigation to follow the perspectives of the successful students, we chose to conduct a naturalistic inquiry.

The Naturalistic Inquiry

Lincoln and Guba (1985) proposed an alternative paradigm to the "rationalistic" method of inquiry. In the "naturalistic" approach, the investigator chooses not to manipulate research outcomes, but to "hang loose" and "hang out", notepad in hand, with the subjects being investigated. Naturalistic researchers go to the particular setting under study because they are concerned with "context". Naturalistic inquiry focuses on "where, how, and under what circumstances." Four of the five subjects evaluated in this study were interviewed independently at their homes or workplaces.

Naturalistic inquiry begins with the researcher determining a focus for the inquiry. Then the paradigm is fitted to the focus. After determining the fit of the inquiry paradigm to the substantive theory selected to guide the inquiry, the researcher determines where and from whom the data will be collected. As the investigation progresses, data collection is constantly adjusted and molded to the initial results. Our investigation was initially shaped by a discussion with the one student who chose not to continue graduate studies in CSD. After an initial interview with one of the successful students, the format and interview design for three other students was developed. When those four students unanimously and independently identified six factors contributing to their success, and those factors were verified by follow-

BEST COPY AVAILABLE

up interviews with three of these students, the lead investigator reached the conclusion that interviews of other distance students were not necessary.

Though out the naturalistic inquiry process, data collection and analysis follows concepts and procedures used in qualitative analysis. The procedures described in Strauss and Corbin (1998) are particularly suited to naturalistic inquiry, so we employed those procedures in the analysis of our results. Qualitative research, as defined by Strauss and Corbin, is "a type of research that produces findings not arrived at by statistical procedures or other means of quantification." Qualitative data, collected from microanalysis, is coded and recoded in a series of steps designed to allow the researcher to detect themes, common threads, and discrepancies. Embedded in the qualitative approach is the step of theory building, which is revisited as the research direction evolves. If any step of the qualitative analysis process should be considered the final step, it would be "refining the theory."

In this study, the ideas that led to identification of six critical factors for success in distance education were tentatively defined during analysis of the contrasts between interview responses of the four successful students and information gathered from the student who did not continue pursuing CSD graduate work. Although initial interviews with the successful students were open for discussion of the entire range of their distance education program experiences, the lead investigator directed isolated segments of the discussion toward problem areas described by the student who did not pursue graduate work in CSD. The six critical factors described in this paper emerged from similarities in descriptions provided by the four successful students, and were verified during follow-up interviews with three of those four successful students.

Factors Critical to Success in Distance Education

This study identified six factors as critical to success in the Consortium distance education masters program. While these factors may have more or less importance in other distance programs, it is likely that most of these six factors are also critical to success in any distance education program in which students have both heavy academic loads and a full time job.

Immediate and Extended Family Support

During the three follow-up interviews, *immediate and extended family support* was identified as the most critical factor for success in this program. In open forums at retreats, students have repeated spoken of the adjustments they had to make in their family and social lives. Those statements support the selection of this factor as being critical to success in distance education. Anecdotes presented include "my husband has taken over the cooking, dishwashing and laundry," and "my friends have learned when they phone me that the first thing they should ask is what is the time limit for this conversation because they know that I will set a limit and stick to it." A common joke among Consortium students is that they are looking forward to getting reacquainted with their husbands after graduation.

One of the authors has tried to recruit several potential distance education students who have not enrolled in the program. More than one of these potential students identified the opposition of their husbands as at least one of the reasons they chose not to enroll. For some other potential distance students, the requirement to be on campus for two summers tipped the scales against enrollment. Certainly, husbands and children had to be accommodating when students chose to spend their entire summer breaks away from home as students, foregoing family and vacation time.

Advisory Assistance

These ASU distance students believed that they could not have made it through the program without a dedicated Campus Coordinator who would give immediate attention to their needs and concerns. They spoke of having faith that the Campus Coordinator would "find a way" when they ran up against university policies that created unnecessary roadblocks because they were written for traditional on-campus students. Certainly distance students face unique problems because they cannot move around campus from one office to another until they find a person who understands specific problems and how to deal with them. Even when problems are easily resolved when you know how to approach them and who to call, those procedures are not always clear to students. On-campus students often find the solution in conversations with other on-campus students. In fact, those conversations often provide on-campus students with a "heads up" about various requirements and deadlines. Distance students need an advocate who will watch out for their interests in that regard.

Being able to call on either the Campus Coordinator, or the Consortium Coordinator, may have given ASU distance students extra security, and may have contributed to their satisfaction with their advisory assistance. Advisors are sometimes out of town, in the hospital, or otherwise indisposed. Since the Campus Coordinator and the Consortium Coordinator of this distance education program have closely coordinated their student support efforts, each has usually been able to at least partially address student concerns when students were not able to reach the other person.

Career Motivation

Students report being "at the end of their ropes," but realizing that they love being public school SLPs and that they do not want to change careers. It is no surprise that having clear educational goals would contribute to a willingness to make sacrifices in one's personal life in order to achieve those goals. Being in a job, liking it, and not wanting to give it up must be a powerful motivator.

Persistence

Some students labeled this attribute as "stubbornness." At times, they did not know how they could continue, but they were not willing to quit. On the surface, this trait might seem equally appropriate for on-campus students, but distance students may need a special kind of persistence because they are isolated. In fact, that quality might be a much better predictor of success in distance education than any of the traditional admissions criteria.

Camaraderie with Other Students

All but two of the sixteen "successful" ASU students began the program with an on-campus summer experience. The bonding that occurred that summer was cited by all of the naturalistic inquiry subjects as vital to their success as distance students. Distance students often become cheerleaders and confidants for each other. At retreats, distance students have spoken of knowing they could call on someone at any time they needed to vent or cry, even at 2:00 a.m. Not being hesitant about calling another distance student may go a long way toward canceling a major negative in distance education, at least for some students. This camaraderie is likely a principal reason that Consortium students have been so positive about their retreat experiences.

Development of Technology Skills

Many of the distance students, especially the older students, were computer illiterate when they entered the Consortium distance education program. Their ability to overcome their lack of knowledge, and even phobia, of technology is undoubtedly a function of most of the other five factors they identified as critical for survival in distance education.

Discussion

Although at least half of the six factors identified as critical to success in distance education by this study were expected, and would probably seem obvious to most educators, at least two factors were somewhat surprising to the lead investigator. Camaraderie with other students is not a common feature of most distance education programs, and is probably often dismissed as an impractical goal by distance education instructors. The students interviewed in this study believe that it was an essential factor in their success, and the student authors recommend that instructors of distance education courses make every effort to facilitate its development.

Advisory support is probably too often taken for granted. Perhaps many instructors do not realize its significance for on-campus students, and assume that distance education students have equal opportunity to access such assistance. It is a factor that can have a major effect on retention and success, and one that is probably too often overlooked because "the resources are there on campus somewhere." There is also the temptation to label additional advisory support for distance students as "expensive," by ignoring the cost of that support for traditional students and the fact that such support is neither efficient nor effective for distance students.

The importance of family support is easily dismissed, since distance education program administrators and instructors are not in a good position to adjust this factor. However, prospective students can be counseled about the importance of this factor. Doing so may be one way to reduce attrition rates in distance education programs.

Evaluation of the Q-matrix Method of Fault Tolerant Knowledge Assessment

Tiffany M. Barnes (tmbarnes@unity.ncsu.edu) and

Donald L. Bitzer (bitzer-m@nova.novanet.com)
Department of Computer Science
North Carolina State University, USA

Abstract – Distance education, delivering high quality, individualized instruction in inexpensive, expandable, and accessible ways is a major challenge for today's universities. This paper presents the most recent work in the field of fault tolerant teaching (FTT). Fault tolerant teaching systems will augment computer-based learning materials with the tools to assess and correct student knowledge. FTT methods automatically create a concept model of an instructional topic, based solely on student responses to tutorial questions, using a statistical method related to data mining. This concept model can be used to assess student knowledge as he progresses through a tutorial, while tolerating the usual errors that occur during testing – such as a student guessing answers or mistyping a response. This paper presents the ongoing results of an experiment designed to test the validity and accuracy of FTT-based assessment methods.

1 Introduction

Universities are now challenged to deliver quality service to students of widely ranging abilities and backgrounds across all distances. To rise to this challenge, distance education must pair individuals with expert instruction that is interactive, adaptive, and accessible. Ideally, computer based educational systems can approximate the benefits of private tutoring at a much lower cost. To deliver this performance, researchers must develop a systematic approach to designing, implementing, and evaluating online educational systems.

One of the main challenges of creating online tutoring systems is knowledge assessment (Stauffer 96, Dietel et al. 91). In other words, a computer tutor must be able to diagnose and correct student misconceptions, and distinguish these from careless errors or guesses. Indeed, much of the research in diagnosing misconceptions acknowledges the importance if distinguishing 'slips' from true misconceptions (Birenbaum et al. 93, Brown & Burton 78, Tatsuoka 83). Once student knowledge is assessed, a tutor, human or computer, must then determine how to best lead a student to reach her educational goals. In many computer-based learning systems, this guidance is based on procedural models for student knowledge (e.g. Brown & Burton 78, VanLehn & Martni 98). However, procedural and other expert-derived models may often fail to diagnose student misconceptions (Brown & Burton 78, Stauffer 96). Because of this and the costly time associated with procedural student models, the Q-matrix method was developed to model actual student behavior and to use this model to diagnose and correct misconceptions (see Barnes et al 02, Birenbaum et al. 93, Hubal 92, Sellers 98).

The Q-matrix method described in (Barnes et al. 02) examines the inputs of many students to automatically extract relationships between questions and underlying concepts, and then uses those relationships in diagnosing and correcting student misconceptions. The Q-matrix method builds in fault tolerance and robustness, optimizes for student performance, and can be used to optimize teaching strategies for effectiveness. This combination of assessment with the ability to optimize teaching strategies will help make it possible to deliver individualized, high quality education at a distance – near or far.

This paper will briefly outline fault-tolerant teaching theory as described in (Barnes et al 02). We will then present our combinatorial experiment designed to test FTT methods in three computer-based tutorials in Discrete Mathematics. In particular, our experiment will examine statistically-derived concept models for each tutorial for validity, compare automated knowledge assessments with instructor assessments, and evaluate the ability of each model to direct remediation of knowledge.

2 The Q-matrix Method

The Q-matrix method uses a body of student responses to questions to create a model of the concepts underlying the tutorial questions. The resulting model is a matrix of concepts by questions, where the value for (c,q) represents the probability that concept c is needed to answer question q correctly. We model student knowledge using "concept states" – bit strings where a 0 means a concept is not understood and a 1 means that it is. For example, the concept state 01 means that a student understands concept 2 but not concept 1. Based on the Q-matrix, we compute an "ideal response vector" for each concept state. Ideally, a student in state 01 would answer all questions needing concept 2 correctly, but would miss questions related to concept 1 – so the ideal response vector for the concept state 01 and the Q-matrix in (Tab. 1) is 11000. While using the tutorial, each student is matched to the closest ideal response vector, and is assumed to understand the concepts associated with the state generating that vector.

	q_1	q_2	q_3	q_4	q_5
c_1	0	0	1	1	1
c_2	1	1	1	1	0

Table 1: Example binary Q-matrix

3 The Experiment

The research reported in this paper is an ongoing experiment to test FTT methods across multiple topics and difficulty levels. We have implemented FTT methods in three NovaNET lessons, testing them with 50 students each, and evaluating the extracted Q-matrices for each lesson. The three lessons include: an existing binary relations lesson, a propositional proof evaluator, and a new lesson in counting. These three tutorials involve problems at several levels of thinking. The proofs program involves synthesis of proofs, a very high level of thinking. The binary relations lesson tests memory and application of definitions, while the counting program spans a wider range of problem-solving skills.

We will compare Q-matrices extracted over multiple semesters for each tutorial, and compare each Q-matrix to Q-matrices developed by experts. We will also examine the extracted Q-matrices for interpretability, and compare their knowledge assessments with those made by instructors. Our goal is to determine what factors affect the extraction of Q-matrices, the effectiveness of their assessments, and their application in directing remediation for students. Along with these evaluations, we will also analyze student surveys, to determine student satisfaction with the tutorials.

The counting tutorial, including lessons in permutations and combinations with and without replacement, was completed and tested with students in Fall 2001. Its interface was built to include the functionality students desired in the binary relations program, including menus for direct access to topics, and keys to move forward and back in the program. Each problem was programmed to randomize numbers in the problems given, and to interpret answers automatically. More in-depth help was also developed for this program, increasing student satisfaction.

The propositional proofs program has offered us the greatest challenge in applying Q-matrix techniques. Since writing proofs is very open-ended, it is difficult to extract relationships between problems. We have designed a solution to this problem. Instead of simply marking whether a student has successfully completed a proof or not, we will also consider each student use of a particular axiom as a question. In this way, we can compare

BEST COPY AVAILABLE

work among students, and create a model that can extract the relationships among proof axioms. This will provide another good test of the Q-matrix method, since axioms can be readily compared to one another. We realize that this comparison of student answers falls short of a full analysis of student responses, and plan to apply several different analyses to student responses to find the best application of FTT methods.

4 Conclusions

The most important aspect of this research is student knowledge assessment. During the course of instruction, the tutorials developed for this research will collect data about student answers and estimate the appropriate knowledge state for each student, without knowing the subject area or specific questions. This estimate of student knowledge will be made based on statistical analysis of a body of student responses to the same questions. Once this analysis relates questions by their underlying concepts, student responses can be diagnosed for conceptual understanding. Using this diagnosis, the tutorial can then tailor the lesson to students' individual needs. In addition, group assessments can reveal which concepts are being taught more effectively, to direct further development of teaching materials.

There are two aspects to evaluating system knowledge assessment. The first aspect is to compare automatic knowledge assessments for each student to those made by the student's instructor. The second aspect is to evaluate the use of this knowledge assessment in directing learning. Knowledge assessments and remediation plans for each student response will be evaluated by instructors for validity. In future experiments, we plan to compare student performance and satisfaction using self-guided work with automated direction based on their knowledge assessment.

If FTT methods can successfully assess student knowledge, this method will provide a powerful tool for investigating teaching strategies: once a student's knowledge state is known, the effects of any teaching strategy on changes in student knowledge can be measured. This research will be the first that we know of to implement a fully automated, general diagnostic tool that can be used to compare different teaching strategies.

The concept structure used for knowledge assessment is also an important outcome of this research. For each tutorial, the extracted concept structure can be examined for interpretability – i.e., for whether the structure makes sense to a human expert. A hypothesis of this research is that this structure will be understandable and usable.

In addition to the analysis of FTT methods, this experiment will also yield knowledge about differences in performance and satisfaction of online education. Students taking the online lessons will be assessed and surveyed and compared with a control group of students enrolled in the same class but not taking the online lessons. It is hoped that students will find the tutorials more effective than self-study, and perhaps at least as effective as in-class lectures.

This research contributes to automating two very important aspects of computer-based education and fault tolerant teaching research: 1) comparing teaching strategies for effectiveness, and 2) determining and correcting student misconceptions. These two results can provide a very strong, scientific basis to the continued development of computer based education and fault tolerant teaching.

In conclusion, this research will provide an experimental analysis of the effectiveness of fault tolerant teaching methods across three topics and difficulty levels, with three groups of students. Regardless of the outcome, this analysis will provide valuable data about the problems of automatic knowledge assessment, and make a significant contribution to the fields of computer based education and fault tolerant teaching.

Facilitation Considerations and Tips for Online Educators and Trainers

Julie Batovsky, Instructional Designer, Syrtis Technology-enhanced Instructional Solutions, Syracuse University, USA,
JUBatovs@uc.syr.edu

Abstract: Online learning is prolific. Advanced technologies are incorporated into education and training as distance learning expands from corporate organizations to universities and new populations of distance learners. Course design must now account for the learner's preferred learning styles, characteristics, and needs while accommodating the learner with less technological resources. This shift to implement an asynchronous technological pedagogical model is necessary to enhance cognition. The shift toward student controlled learning requires extensive preparation by both facilitators and students, a shift it does not appear they are currently prepared for. Technology allows for the exploration of various learning options. A shift toward student controlled learning requires extensive preparation by professors and students. Technology-enhanced instruction can be used to enhance cognition when used in conjunction with principles of instructional design. Supported by powerful technologies, students can become responsible managers of their instruction, and instructors can become enabling facilitators and co-learners.

Streaming Media Spending to Hit $5 billion per year (n.d.) Retrieved November 30, 2001, from http://www2.cio.com/metrics/2001/metric253.html

U.S. Web Sites Integrating Training Education (2001). Retrieved November 27, 2001 from http://www.idc.com/ebusinesstrends/ebt20010927.stm

Introduction

It is estimated that by the end of 2001, about 38 percent of U.S. organizations will have integrated education and training with their web sites (U.S. Web Sites Integrating Training Education). It is likely that more advanced modes of technology such as streaming media, voice and pattern recognition, wireless devices, and virtual reality will start to be incorporated into education and training solutions in 2002. Spending on streaming media services for example is expected to surpass $5 billion per year by 2005 in corporate organizations (Streaming Media Spending). Distance learning is expanding from corporate organizations to universities and new populations of distance learners are emerging. Course design in distance courses should account for the learner's preferred learning styles, characteristics and needs while at the same time accommodate the learner with less technological resources available to them (Flowers). Also important in course design and implementation is recognition that a shift from a teacher-to-student model to a technology-enabled interface to fit individual learning styles and needs is occurring. This shift to implement an asynchronous technological pedagogical model is necessary to enhance cognition. The shift toward student controlled learning requires extensive preparation by both facilitators and students (Johnston & Cooley), a shift it does not appear they are currently prepared for.

Recommendations

In a report submitted to President George W. Bush by the President's Information Technology Advisory Committee (PITAC) in February 2001, the overarching recommendation of PITAC was to "Make the effective integration of information technology with education and training a national priority." The PITAC recommended that the following four specific actions occur at the Federal level:

1. Establish and coordinate a major research initiative for information technology in education and training.
2. Establish focused government-university-industry-foundation partnerships to aggressively pursue the information technology research program required to advance education and training technology in the United States.
3. Enable educators and related professionals to use information technology effectively.
4. Develop and promote standards for education and training.

With recommendations to research and better enable educators to use information technology, the PITAC report indicates that educators are not yet effectively integrating information technology with education and training. The focus of the research that follows deals specifically with number three, enable educators and related professionals to use information technology effectively. Discussion will for the most part be limited to the technology currently available to online facilitators. Please note that this discussion does not differentiate between education and training. While these settings differ, education and training are both forms of learning and the information technology is adaptable to both settings (PITAC, p. 3). By identifying considerations and providing tips for facilitators of distance education and training, I hope this discussion becomes a useful tool to those educators to begin to integrate currently available information technology more effectively.

Considerations

Instructional design is "systematic instructional planning including needs assessment, development, evaluation, implementation and maintenance of materials and programs" (Richey, p. 181). Many educators are being required to design and implement online courses without much (if any) lead-time. This short lead-time may eliminate the ability to conduct a needs assessment, or properly conduct a formative evaluation cycle prior to implementation of learning in this new environment. They are asked to develop web sites or use learning management systems (LMS) with little or no training on how to do so effectively. Research cautions educators not to make the mistake of recreating a classroom-teaching model within an online learning environment during course design (Sonwalkar, p.11). But how can educators possibly determine the needs of their new audience, learn technical issues, identify constraints, identify standards (or lack thereof) for each LMS, and modify the course's design to be student controlled given short ramp up times?

To answer this question let us turn to the role of the educator or trainer in the online learning environment. I would argue that their role is that of a facilitator. What then is a facilitator? Merriam-Webster's collegiate dictionary defines facilitate: "to make easier : help bring about". Given this definition the term facilitator seems appropriate for the online educator or trainer. With the shift to a student-centered learning model in distance education, the role of the educator or trainer is to facilitate learning – to make it easier for students to learn. This is accomplished by:
- Making it easy for students to communicate their experiences, thereby enhancing them.
- Encouraging and helping students to reflect upon their experiences.
- Assisting students to develop their own learning processes, making them better learners.

This approach keeps the focus on the student and focuses on "what learners experience and how learners learn from these experiences" (Greenaway).

Facilitation Tips

When creating online courses, facilitators should allow plenty of time prior to the start date for development. Since creating new subject matter while building an online course may overload an individual, an educator or trainer should consider converting an existing course rather than creatinga new one to start. For facilitators who are not familiar with web site development, LMS tool kits are designed to manage courses and course materials. Some of the features provided by LMS include helping facilitators to communicate with students, track student web site use, and administer online surveys and exams (Demystifying Learning Management Systems). Links to web sites may also be included if a combination of web site development and LMS features is desired.

Facilitators should attempt to exploit the full power of online learning by making the course content interesting. When possible, they should allow the students to create some of the topics so that they have a vested interest and so they can anchor new information to their previous life experiences. Even when students help create topics the facilitator should structure all activities and specify objectives clearly and in detail (Klemm, 1997). Students may be asked to conduct "debates" where each student is asked to take a position on and post supporting arguments for or against the topic as well as critique other arguments (Klemm, *n.d.*). The PITAC report agrees that assignments should be sequenced to help students comprehend and piece together information, establish a broader context, promote discussions, evaluate results, and be redirected as needed (PITAC, pg. 9).

To ensure students receive a high quality, online learning experience attention should be given to the depth of content, accommodations for significant interpersonal interaction, and the facilitation of a wide variety of learner needs and capabilities (Flowers). Facilitators should determine the learning preferences for the current group of learners and structure course activities appropriately to aid their learning. Soles suggests online distance learning activities appropriate for each Myers-Briggs learning preference in Table 1. Online Distance Learning Activity Suggestions for Myers-Briggs Preferences.

Myers-Briggs Preference	**Myers-Briggs Learner Traits**	**Online Distance Learning Activity**
Introverted and Sensing Learner (IS)	• Thoughtful realist. • Knowledge is important to them in establishing the truth. • Perform best when dealing with what is real and factual. • They can work in a careful unhurried method.	• Asynchronous • Problem-solving case studies • Critical analysis of real-world situations • Project that allows planning, practical application of concrete principles to real world situation • Requires and allows time for research and reflection • Learning contract
Extroverted and Sensing Learner (ES)	• Practical realist. • Knowledge is important to them for practical purposes. • Perform best when they are dealing with concrete factual information and the practical information of the information is obvious.	• Synchronous, video conferencing. • Real-life case studies • Problem-solving exercises that focus on facts and practical information. • Learning contract
Introverted intuitive Learner (IN)	• Thoughtful innovator. • Knowledge is important for its own sake. • Perform best when dealing with concepts, theories and to achieve a depth of understanding. • Like to work in a scholarly, introspective fashion.	• Asynchronous • Critical analysis of new ideas, possibilities • Research exercises • Reflection journals • Formulate hypothesis exercise
Extroverted intuitive Learner (EN)	• Action-oriented innovator. • They see knowledge as the basis for creating change. • They perform best in new situations and they see challenges as opportunities to make things happen.	• Synchronous, videoconferencing • Collaborative exercises • Brainstorming exercises • Problem-solving case studies • An unstructured, construct-as-you-go activity with a variety of options.

Table 1. Online Distance Learning Activity Suggestions for Myers-Briggs Preferences

Activities should be carefully selected to stimulate reflection, insight, integration, creative or critical thinking, or in-depth problem solving. To achieve this, try using team-learning techniques. Group interaction is enhanced through cooperative learning and an increased access to experts (PITAC, pg. 6). Working in teams, students are likely to form bonds with one another and become more likely to participate in other online conference activities.

Learning can be encouraged by assigning students to research information on assigned topics, piece it together, report the information and discuss it with the class (PITAC, pg. 8). In his paper "Eight Ways to Get Students More Engaged in Online Conferences", Klemm's first solution is to make participation a required portion of the course grade. He believes that this will engage the student and produce thoughtful responses because students will not want to post low quality postings for peer review. Several authors also suggest that the facilitator become actively involved in the conference. Students benefit from the knowledge, experience and insight offered by the facilitator. To further allow students to integrate, synthesize and apply information they find through research, facilitators should consider requiring a deliverable or term project that captures a main topic of the course.

Finally, remember that each group of learners is different and things will not always go as planned (this is no different than the *classroom environment). As a result it is required that the facilitator* be a good troubleshooter and problem solver. In the event the problems are technical, it is helpful to have technical support available and know how to use it.

Greenaway suggests three strategies to turn 'intrusive complicators' of online learning into enabling facilitators.
1. Ask learners what is helping and hindering their learning.
Conduct formative evaluation while working with learners. The insights and perspectives from the students on the learning process can help identify the learning strategies that are the most successful.
2. Demonstrate confidence in the process of learning from experience.
Being a facilitator also means empathizing with the students and actually becoming a learner. By becoming a better learner you will become a better facilitator.
3. Notice the realities and possibilities with the current group of learners.

Working with current experience matters more than what worked well in another time and place with other people. Our experience and knowledge of 'similar situations' or 'familiar types' is useful background but no more than this. We can draw from our past experiences, but they should not overshadow our present experiences. How we work should be a creative response to the current situation.

Conclusion

For better or worse, technology has already changed the educational environment in ways that educational leaders must recognize and address. Expectations regarding new technologies will rise as they continue to be implemented in more organizations. As the standards continue to emerge in the area of learning management systems and other education and training solutions, both students and facilitators must be educated so that they may better comprehend their new and emerging roles in this instructional environment. Pedagogical models will continue to evolve and be redefined to better design, develop and evaluate instructional materials delivered via these technologies. Educational leaders should continue to conduct research on learner styles, characteristics and needs so that instructional goals, activities, etc. may continue to be updated and improved.

Not all students and not all instructors, facilitators or faculty are comfortable with this shift to student-led inquiry or problem-based learning. Some still prefer more traditional models. Technology allows for the exploration of various learning options and ability to account for different learning preferences. A shift toward student controlled learning requires extensive preparation by both professors and students (Johnston & Cooley). Technology-enhanced instruction can be used to enhance cognition when used in conjunction with principles of instructional design. Supported by powerful technologies, students (especially those who have grown up with powerful technologies) can become responsible managers of their instruction, and instructors can become enabling facilitators and co-learners.

Online Course Design: An MBA Course Example

D'Arcy Becker

USA
dbecker@uwec.edu

Abstract: Course design is the key to student learning, whether the course is taught in a traditional setting or online. Research espousing the benefits of online courses routinely refers to the ability to help students learn in a constructivist manner when using online resources. This paper presents a detailed analysis of an online MBA course, Introduction to Assurance Services, which was designed with much of the current research on constructivism and online courses in mind. The paper outlines the assignments and the rationales for using them; it also presents student reactions to the assignments.

Introduction

The recent trend of placing courses online is having a profound impact on higher education (Bennett 2001), although many questions concerning the value of online learning remain unresolved because of a limited amount of scientific inquiry into the effectiveness of online instruction (Spector 2001). Theoretically, quality need never be compromised when a course is delivered online; online courses should provide learning experiences that are at least as meaningful as courses using traditional teaching methods (Hobbs 2002). Online instruction may even be superior to traditional methods for some content and some students, helping reach students with diverse learning needs (Ross and Schultz 1999). Online MBA courses may offer advantages over traditional MBA courses that are often overlooked, including the unique possibility for greater appreciation of content, and the ability to instigate creative and critical thinking (McCallister and Matthews 2001). Course design may determine whether online students reap these learning benefits.

This paper describes an online MBA course, Introduction to Assurance Services, and provides data on the effectiveness of course learning components from the viewpoint of students in the course. Assurance is an independent professional service that improves the quality of information for decision makers. Experts provide oral or written testimony that the assertion of another party meets (or does not meet) specified criteria or standards. Examples include whether a company follows a stated process for handling customer returns, whether credit card information is kept securely, whether child labor is used to produce a product, and whether the percent of money a charity uses for charitable purposes is as high as claimed.

Major elements of the course were designed in accordance with constructivist learning theory. Constructivism is not a teaching theory but instead a theory on knowledge and learning. Its basic premise is that students can actively construct their knowledge, thus modifying their understanding, by assimilating new information with prior knowledge and promoting active and cooperative learning (Bennett 2001). Constructivism emphasizes the learner's role in constructing meaning as opposed to simple transmission from teacher to student (Wilson and Lowry 2000).

Student Characteristics

Nineteen students all had basic background in business courses but need not have had prior online courses or any specific course content prior to enrollment. The course ran for four weeks on the web-based system BlackBoard. All data reported below were obtained via two student surveys. Students who did not return surveys were contacted with email reminders, which resulted in a 100% return rate for each survey.

Average years since undergraduate degree was 7.5 years (median 5.5). All students except one were working full-time during the course. Students worked in middle and upper management at companies varying in size from five employees to multinationals. Every area of business was represented, resulting in students bringing a wide variety of backgrounds and experiences to the class. Some course elements were specifically designed to take advantage of this variety.

The average number of prior online courses was 2.94; sixteen students had at least one prior online course. Eleven students reported routinely taking a lap top computer along on business trips; eleven students reported routinely engaging in ecommerce transactions (such as buying online). All students reported using the Internet outside of class or work for at least three hours per week (average 6.6 hours/week). Students reported they had been using the Internet an average of 5.9 years; one student reported belonging to an Internet chat group. Fifteen students obtained course access via dial-up modem, three obtained access via cable modem and one obtained access via DSL phone service.

Overview of Course Design

Course information was taught in two units, each of which contained multiple lessons. The major goal of the first unit was to have students learn background information about assurance services. The major goal of the second unit was to have students investigate real-world applications, identify situations when assurance was needed and assess its quality in various contexts. This type of modular design for online courses has been advocated in the education literature; the function of the modules is to deliver course content and make available all necessary information to meet the learning goals, including the opportunity to put that information together in a meaningful way (Tilson, Strickland, DeMarco and Gibson 2001).

A key component of an ideal online course, the course calendar (Carr-Chellmand and Duchastel 2000), provided information about all assignments and deadlines. The outline listed the due date for every assignment along with its point value and referred students to the details about each assignment that were stored in a course materials folder in BlackBoard. This outline helped students see the workload over the entire course to enable them to adjust their schoolwork to fit their work schedules. Only one student (who had no prior online course experience) had a difficult time following the schedule; he mistakenly believed the course would run like a correspondence course, allowing him complete flexibility in meeting assignments.

Constructivism does not imply certain specific teaching methods (Wilson and Lowry 2000); this course used a variety of teaching techniques including lectures, web-based research, papers and discussions. The Internet affords the opportunity to use multiple representations of knowledge and a way to sequence that information in a way that makes pedagogical sense (Arnone 2002). This course centered around Internet use and followed the three core principles for effective use of the web in teaching as proposed by Wilson and Lowry (2000): access to rich information sources was provided, meaningful interaction with content was encouraged, and students were brought together to challenge, support and respond to each other.

Each lesson contained readings including an online instructor lecture and online business press articles; reading guide questions were provided to add structure. Each lesson also contained online research activities, some of which were completed individually and others in groups, as described below.

There were three small group (three students per group) discussions and one class-wide discussion. For small group discussions, the instructor assigned students to groups and different pairings were used for each discussion. Students were always paired so each group member was from a different school, so there was no possibility of in-person communication among students. Participation in all discussions was monitored to assure a minimum of free riders. For the first discussion, the instructor sent messages to all students regarding their participation in an effort to make discussion monitoring more visible. Shortly after the discussion period ended, all students received their discussion participation grades, which helped ensure students understood the expected level of participation.

Gaining an Understanding of Assurance Services

Students benefit from applying concepts in specific contexts; when concept and context are separated, knowledge is seen by learners as the final product of education rather than as a tool to help solve future problems (Herrington and Oliver 2000). Further, learners bring their own experiences to learning situations, and those experiences help set the context for new knowledge by helping learners construct new knowledge (Grabinger 1996). In unit one, students held a class-wide discussion in which they posted examples of assurance services being used by their employers (along with a description of their current position and employer). Each student responded to at least one example, engaging in a discussion of the apparent usefulness (or lack thereof) of the assurance example.

Interaction with a series of real events or examples has also been shown to help learners develop a deep level of competency (van Merrienboer 2001). Therefore, the next lesson required an investigation of common applications of assurance in e-commerce. The goals of these investigations were to illustrate the necessary components of assurance services and to enable students to understand how and why companies provide assurance information. Students wrote papers about the use (or the potential use) of e-commerce by their employers and the need for accompanying assurance information.

To develop further understanding of the connections between the goals of assurance and the kinds of assurance disclosures organizations make, the issue of social audits was highlighted. Students read background information about social audits and then examined two companies' disclosures: The Body Shop Inc. and Citizen's Bank of Canada. The companies' disclosures were evaluated for thoroughness and quality; students wrote papers addressing the inferences they had drawn about the companies' reasons for making the disclosures. Students also examined social audit disclosures made by The Gallup Poll and held small group online debates about whether these kinds of disclosures meet the requirements of assurance services (they generally do not).

Students found the initial discussions very helpful in making assurance services seem relevant and in helping them identify a wide range of types of services. Fifteen of 19 students reported this discussion as very interesting; all felt it led to either a modest or large increased in their knowledge of assurance services. Students reported this critical review of information increased their knowledge of assurance and helped them better understand the use of assurance services across a broad set of business applications.

Application of Knowledge to the Real World

The second unit of the course allowed students to enrich and deepen their basic understanding by focusing on socially responsible investment mutual funds' disclosures of investment criteria and related information. These funds attract investors by promising to make investments in companies that meet a defined set of social responsibility criteria, which provides an ideal setting for assurance. Students each investigated a fund that claimed to follow a social responsibility philosophy; no two students investigated the same fund. The only restriction on fund choice was it had to be listed in either www.socialinvest.org or in www.socialfunds.com. This was the first time students found their own examples and investigated them; in all prior course assignments, students were directed to specific examples of assurance.

The funds provided an authentic context for studying assurance. Adults learn best when knowledge is presented in a real-life context (Huang 2002) and involves experiential learning (Harper, Squires and McDougall 2000). This assignment also allowed students the freedom to explore Internet information on these funds, thereby permitting students to construct individual learning experiences (McCallister and Matthews 2001).

Students wrote individual papers addressing the investment criteria, purposes assurance services might serve and the quality of the assurance information provided by their funds. Next, students held small group online debates about which fund had the best example of social responsibility criteria and accompanying assurance that the investment criteria were being followed. To participate in this debate, each student posted a summary of their individual findings and nominated it for consideration (or no consideration) as "best". Each group formed consensus about one fund and submitted a group paper explaining the group's conclusions.

Students found these investigations helpful in enhancing their understanding of assurance services. When asked whether there was another decision setting they would rather have investigated, 18 of 19 students replied no. Students also reported the project as interesting and informative because it addressed a current business controversy, was something they can relate to in their business, and helped them see the wide range of information available and evaluate that information more rigorously.

Rating the Assignments

When asked to rank the seven major course assignments according to the amount learned, all students rated the employer examples class-wide discussion either as one or two. This is not surprising given that it was early in the course when many students still have relatively vague knowledge of assurance, and the fact that this assignment allowed students to see concrete, interesting examples from actual businesses. The next most popular assignment was the socially responsible investment fund paper.

Interestingly, the third most popular assignment was the guide questions provided for each reading assignment. Gupta (2002) states that just posting lecture notes, assignments and the solutions does not help the student in E-learning. While these assignments would not fare well if they were the sole learning opportunities, such learning elements may play an important role in an online course. In this course, many students found this traditional course element helpful in focusing on the important aspects of the material. Online courses should not eliminate any one type of assignment but instead should consider how best to incorporate many types.

Conclusions

This course allowed students to capitalize on advances in information processing and the Internet. There was a high level of interactivity between the instructor and students as well as between students as is suggested in the literature (e.g. Sampson, Karagiannidis and Kinshuk 2002). Students' individual backgrounds were used to enhance learning, as was the wide variety of information available online. Most assignments used Internet information and would not have been possible without its use. Students reported learning a lot from the assignments and did not seem to feel negative effects from the lack of face- -to-face contact time. Online courses, designed and executed well, can provide a high quality learning experience.

Digital Literacy and Reflective Competencies

Claire Bélisle
LIRE-CNRS-Université Lumière Lyon 2,
France
claire.belisle@ish-lyon.cnrs.fr

Abstract: The competencies teachers need to integrate information and communication technologies in their practice are just beginning to be identified. This paper argues that the most productive way to integrate the emerging digital culture in the fields of education and training is to have teachers become "reflective practitioners" as they acquire a mastery of the technological basis of this culture. The traditional teaching competencies, applying problem solving strategies to well defined problems, need to be augmented today with competencies that can deal not only with 'indeterminate zones of practice' but also reframe goals and problems as educational paradigms and landmarks are questioned.

*E*learning has raised many hopes as an entry point into a digital XXIst century. In the European context, *e*learning corresponds to four types of objectives; there are first equipment objectives, aimed at providing teachers, trainers and learners access to online multimedia resources in every learning and training institution; secondly, digital literacy must become an integral part of teacher training, whilst learners develop a critical approach to learning with ICT (Information and Communication Technology); a third objective is the development of a multimedia content industry and of services; and, finally, accelerating a complete networking between teaching and learning institutions. This paper examines the second type of objectives, bringing digital literacy into learning environments and ultimately to learners. The background material is a report on user studies of ICT integration in education and training (PNER, 2002). It will be argued that, because the new competencies of digital literacy are just beginning to be identified, the most productive way to integrate the emerging digital culture in the fields of education and training is to have teachers become "reflective practitioners" as they acquire a mastery of the technological basis of this culture. This however is not the dominant approach. ICT integration is usually presented as lying within the conventional boundaries of professional competence of teachers, provided acquisition of complementary technical skills.

Integrating Technology

The methods used to implement technology have been very much dependent on the conception of learning dominating the field at the time of the technological implementation. Computers were initially integrated into teaching and learning in the seventies in a behaviourist approach. This paradigm, based on an objectivist epistemology, sees knowledge as externally mediated information which a teacher transmits to a learner. Learning is therefore acquiring existing knowledge. Information and knowledge are interchangeable and are externally referenced. Therefore the drill and practise applications were by far dominant as were the modular design of educational contents geared to acquisition of objective knowledge.

Reference to a constructivist epistemology has now become dominant in the integration of technology in education (Becker & Riel, 2000). In this approach, technological tools are interesting inasmuch as they become cognitive tools, that is tools that amplify thinking processes and help learners to develop their own knowledge, based on the constructs and processes provided by their environment. Integrating multimedia in learning activities is intended to extend cognitive functioning during learning, to facilitate cognitive processing, to support, guide and extend the thinking processes of their users. However this approach produces qualitative results and leaves managers, producers and decision makers, working within the technical rationality approach, lacking clear cut guidelines, rules, norms and specifications for design and implementation in schools.

These approaches have both brought to the fore broader questions and challenges about information, knowledge and schools. Web use and hypermedia are associated with portals, maps, visualisation, or guides and tours. Navigation is integrated as an alternative to classical information retrieval through query and answer process. Apart from the way navigation is used to find information, one very important aspect is the way navigating in information resources is bringing about a different way of reading, of interpreting texts and images and of constructing meaning. Research on hyper-thinking or thinking processes involved in the use of hypermedia or information resources structured by hyperlinks, has shown that new cognitive patterns are beginning to emerge in user conduct (Nunberg, 1996).

Multimedia gives access to metaphorical thinking. Analogy is a basic process in thinking and especially in learning. It is used to describe objects or to explain how a mechanism functions in reference to another object already known. With the development of 3D graphics, of haptic or tactile experiences of virtual reality systems, a new relationship to information is gradually emerging, based on sensory experience, visual deployment and *multi-referentiality*. Multiple knowledge sources, that began with television and CD-Roms and are now implemented by advance communication technologies, are more and more integrated in uses and practices. Should they also be integrated in teaching and learning practices? Can knowledge be constructed using multiple modalities?

Fostering A Digital Literacy Culture

Many learners, teachers and trainers are now computer literate: they can generally use without needing outside help word processors, spreadsheets, graphic applications, electronic mail, CD-ROMs, and hyperlinks. This integration of IC technology by teachers in their daily practices at work and at home has meant not only familiarity with technological tools as such but also becoming aware of what these tools enhance, of what they change and of what they empower.

Literacy for the digital era requires new core competencies that have been described under the term of "digital literacy" as "the ability to understand and use information in multiple formats from a wide-range of sources when it is presented via computers"(Gilster, 1997). Literacy can be understood as encompassing "a complex set of abilities to understand and use the dominant symbol systems of a culture", multimedia literacy skills as a combination of computer literacy (understanding of hardware and software) and media literacy (ability to access, analyse, create and evaluate information through a variety of media). More specifically, these competencies have been analysed as new analytical/critical thinking skills and production skills. Identifying them is part of the solution, but the most difficult part is bringing them about, having them emerge in the educational situations.

Integrating ICT in education and training brings about important changes concerning the way educational problems are identified, addressed and dealt with. Mediating contents and interaction by technology obliges to a very exacting and precise organisation of learning situations and learning contents. Multimedia makes a difference when it is integrated as an interactive dimension in learning, when its multimodal dimension activating multisensory experience is elicited, and when its hyperlinking functionalities are exploited to bring about rich semantic experiences. Teachers and trainers have found that these technological tools have led them to important changes in their activities and their daily routines, that they have had to re-elaborate their conduct by letting the technology take over certain tasks and by developing new ones. Accounts of these changes in user studies testify of the complexity of the issues involved.

As many teachers found out, integrating technology entails constraints and requirements. It has meant moving from products to processes and from developing curricula to implementing learning environments. It involves domesticating technology to enhance human learning experiences. It brings about a new approach to educational resources with their formatting for wide range use. It requires addressing ICT literacy and leads to re-negotiating educational aims, methods and evaluation procedures. The technological tools need to be enhancing processes involved in the learning/teaching/training activities. Learning happens in a learning environment when motivated learners decide to interact with learning materials. The specific characteristics of the teaching and learning situations have to be taken into account.

Competencies For New Information Challenges

One of the most interesting characteristics of the multimedia technology is the possibility of accessing vast resources of information and alternatively of making available at apparently little cost vast resources that were dormant in drawers, schools or libraries. But the advantage of the networked information technology is also its drawback. The huge amount of information available diminishes the chances of finding the pertinent or specific information that one is looking for. Even though education and training communities usually have access to these large knowledge resources, most teachers work with paper information whether in itself or through bibliographical descriptions. Handling large amounts of digital information is still a relatively new situation. Unsurprisingly, interaction with information has now come to the forefront as an urgent and complex problem for the information society and more specifically for education.

But most importantly, the integration of ICT brings about new 'indeterminate zones of practice', 'situations where there are no right answers or standard procedures', with 'decisions that have to be made under conditions of uncertainty'. This can be seen in the evolving interaction with texts, information, and knowledge. For example, the printed book has brought about a representation of knowledge as established, universal and stable. The web offers knowledge that is under discussion, coming from varied sources and constantly being updated. How can these two representations refer to common grounds? Another example is the problem faced by teachers when students reproduce information texts without referring to their sources: with whom will they discuss this important issue of imitation and whether or not it is legitimate learning to 'borrow" literary content without acknowledging it.

The formatting and labelling of information for machine retrieval is no small decision. Who will be making it? It also means that teachers need to become familiar with research results, such as those of the Dublin Core work group on metadata, and to combine them with a reflection on their practice in order to be competent to interact with an emerging educational semantic web, that is with machines capable of analysing the educational data on the Web: the content, links and transactions between people and computers. Having to describe educational contents, or producing meta-information on learning and teaching contents, is not a new task in itself, but making it a competence of every learner, teacher or trainer is a new challenge which can bring about a deeper understanding and mastery of knowledge.

In such a context, automating information research and retrieval appears strategically as having high priority. Structuring information in a database and providing the necessary descriptors for formatting the information in a manner decipherable by machines implies using tools teachers are not familiar with. Research on metadata or machine readable description information about an information source is one of the solutions being researched. The use of a machine readable syntax included in the information resource is what the Semantic Web approach is trying to implement. As Tim Berners-Lee wrote, " *The first step is putting data on the Web in a form that machines can naturally understand, or converting it to that form. This creates what I call a Semantic Web, a web of data that can be processed directly or indirectly by machines.*"

IC technology in a learning environment is not only a means of transmitting and storing information, but also, if not mainly, a means of facilitating interaction with information, that is generative processing, relating new information to prior knowledge, activating appropriate schemata, interpreting new information and inferring new knowledge. This is a very indeterminate zone of practice at the present time and needs to be explored by practitioners engaged in everyday teaching activity. Informed decisions need to be based on a reflective practice of using such resources in actual teaching and learning situations. Will the classroom situation and the face to face interaction become more and more blended with online distant learning? What will be the contours of the teaching-learning activity, as information resources grow and their access becomes more and more user friendly?

Schön's ideas, as voiced in his seminal work "The Reflective Practitioner" (1983), have been largely integrated by the educational community. Reflective practice has shown its benefits for teaching and for teacher training and ongoing training programmes have integrated reflective thinking geared to action. (Beedle, 2002) Yet, even the "enriched reflection", based on personal professional practice and helpful examples, of Penny Ur (2000) remains within the 'planning to evaluation' cycle. It falls short of taking into account the questioning of the very aims of teaching today and of the consequences for learning. The kind of competencies needed by teachers to cope with the new resources and demands of information and knowledge, and the digital literacy that it entails, cannot be acquired by reflection on action alone. The traditional teaching competencies, applying problem solving strategies to well defined problems, need to be augmented today with competencies that allow teachers to identify and elaborate new problems and questions.

Teachers have been invited for some time now to experiment the uses of ICT in their practice. They are therefore already in the midst of new situations involving ICT and have been reporting on these situations for some time now. User studies and use account by teachers have produced many findings that remain largely dormant, because of their local validity. However, teachers could gain much more insight from these studies and become more apt to reflect on their own practice, if they had access to some 'experience in the methods of normal science research', a 'superb preparation for reflection-in-action" (Schön, 1987). Scientific research begins by questioning the frontiers of the initial problematic situation and by redefining what is at stake. For example, the use of collaborative technologies could lead to taking into account the findings on co-operative vs. individual learning and the social psychology findings on group dynamics and group work; the introduction of video and graphics could result in the exploration of cognitive psychology findings concerning mental imagery, illustration, visualisation and cognitive processes. Or course development of some of these competencies is already taking place, but at a very discrete scale.

Implementing a 'reflective practitioner' approach within the training of teachers and as part of their daily practice, when integrating educational multimedia in schools, could lead to the development of core digital culture competencies for teachers. Some of these competencies are similar to those requested in research and can be developed through a systematic initiation for student teachers to research procedures and processes. This would mean opening up the reflective practitioner not only to pedagogical issues and problems, but mainly to framing, and dealing with, the new equilibrium, between school and society, of information management and knowledge construction.

Abstract: To take advantage of the asynchronous telelearning, documents representing courses must fit appropriate characteristics. The most important of these characteristics is the ability of the courses to adapt itself to the learner profile. The courses must also be interactive, structured, multimedia, web compatible, etc.

The purpose of this paper is to show how using XML and its associated tools is the way to fit all of these characteristics. It also describes the manner these characteristics are integrated.

Introduction

This study is a part of the SMART-Learning (System for Multimedia Adaptative and coopeRative TeleLearning) project at the RIM research unit (Réseaux Informatiques et Multimédia) at EMI. The goal of this project is to provide courses to distant learners without any space or time constraint, including the possibility of having synchronous sessions (real time) for the conversation between the various actors intervening in the process of learning (learners, trainers...). In addition, the fundamental goal is the adaptability of the courses to the learner according to pedagogical requirements and learner capabilities (Benkiran 2001).

Generally, courses that are available on the Internet are hypertext documents. The structure of the hypertext and the reading modes it leads to are opposed to some educational principles. A learner can access any pedagogical sequence of a course without order constraints of these sequences and without having the preliminary knowledge. Consequently, the teaching objectives aimed by the access to the course will not be reached. In our view and to ensure a pedagogical learning, the course must take account of the learner profile (capacities of training, previous knowledge, language,...) and the learner evolution (prerequisite, speed of knowledge acquisition...) (Ajhoun 2001).

Another limitation of the hypertext is that the course has no structure and its content is mixed with presentation markers, which makes it impossible to automatically process the course.

In order to meet the courses needs in telelearning, it is necessary that the course document fits the following characteristics:

(i) The course must be a hypermedia or at least a hypertext document, in order to guarantee the interactive aspect of the course,
(ii) It must moreover be written in a syntax allowing it to be put on the Web,
(iii) The course document must be able to reproduce the course structure and contents,
(iv) It must also be modular. A course part can be added or updated without changing the whole structure,
(v) The document must be structured so that its manual or automatic processing is easy,
(vi) The course document must respect a course model previously defined on pedagogical bases,
(vii) The structure as well as the content must be independent of the presentation aspect of the course in order to allow the modification of the document style in a global and content independent

manner,

(viii) The course is a hypermedia document that must be able to guarantee the synchronization (or scenarization) of the media it contains,

(ix) Finally and overall, to guarantee the adaptability of the courses which is a very important feature allowed by the telelearning.

We will show, in the continuation of this paper, how XML and its associated tools make it possible to guarantee, to the documents which represent our courses, the characteristics that we have just listed. We applied and tested these methods in our SMART-Learning system.

Course Characteristics in SMART- Learning

SMART-Learning is mainly asynchronous. It provides courses to distant learners without any space or time constraint. The objectives of the SMART-Learning course structure is to fit the characteristics defined above and take advantage of the asynchronous telelearning.

The power of SMART-Learning appears in the ability of the courses to be adapted according to the learner profiles, as well as the ability of cooperating through the document.

We are mainly interested in presenting the model for structured and adaptative courses in the Internet (characteristic (ix)). The course structure is essential to satisfy the objectives listed above including the adaptability objective in SMART-Learning. It must allow the production of a generic course which will be used to generate a specific course at the moment of the training (Fig. 1). This model provides the general structure of a course in such way that the sequences presented to the learner are adapted to his profile and to the training level he wishes to reach.

Figure 1 shows how adaptability is processed in SMART-Learning. This schema will afterwards be realized using XML technology which is the only one that allows, in the same time, the adaptability and the other characteristics.

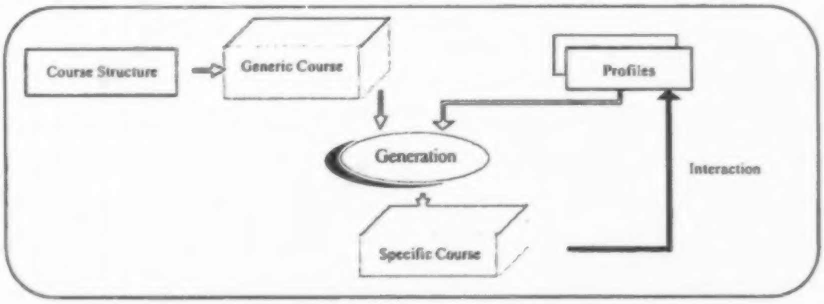

Figure 1: Learning Process in SMART Learning

This approach makes it possible to generate for each learner, based on his profile, a specific course by using a generation system (Fig. 1) during the training while the learner is accessing the course. If, for example, the learner profile is modified following the result of an evaluation, the course will be automatically regenerated so as to consider the new knowledge obtained by the learner.

Course Structure in SMART-Learning

In order to fit the above listed characteristics as well as the pedagogical process, we defined a structure for the course document of SMART-Learning which will be then represented in XML. The production of a course is based on an educational design, which is used to structure the contents in order to facilitate the learning. The course structure must take into account the following criteria (Fleury 1994):

- To stratify information in order to take account of the complexity levels and to adjust it with the preliminary knowledge of the learner (characteristic (ix));
- To structure the presentation in media elements in order to facilitate the selection, the organization and the integration of information to be presented to the learner (iii, vii, ix);

BEST COPY AVAILABLE

- To produce the course in several languages in order to improve its deployment for a larger number of possible learners (ix);
- To consider the use of various media (text, audio, video...) which encourages the learner to take a telelearning course (i, ii, viii),
- To have a hierarchical structure to represent the course document (iii, iv, v).

The generic course is then seen like a set of pedagogical sequences (PS) structured as a tree with a single root. Each sequence constitutes a distinct whole. It can be a course, a chapter, an evaluation or other. A pedagogical sequence (PS) is then broken up into other pedagogical sequences or elementary pedagogical sequences of the lowest granularity. The leaves of the tree constitute the contents to be presented to the learner, they are the media elements (ME). For adaptability reasons, each component (PS, PSe and ME) is annotated by a set of selection criteria which will be used by the learning process in order to generate or not the component according to the learner profile at a given moment. Thus, we defined four categories of selection criteria : Educational, psychological, localization and technical.

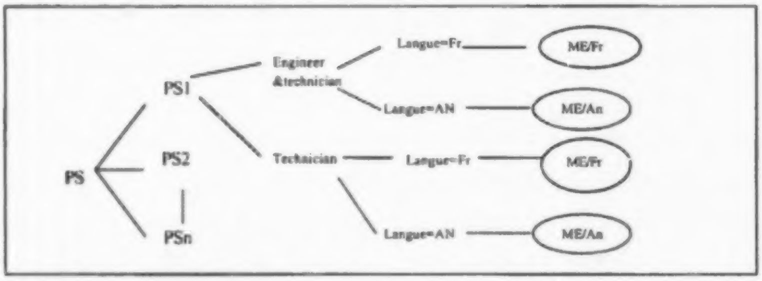

Figure 2: Example of relations between the criteria

XML as a Solution

The XML language, reputed by its facility to exchange complex document on the Internet, is in fact the ideal solution to fit all SMART-Learning and telelearning courses characteristics we defined earlier. XML comes with a set of tools based on XSL, DTD-Schemas, CSS and parsers.

Hypermedia Structured Documents on the Web

The eXtensible Markup Language (XML) allows to write hypermedia course documents (i, ii) just like the HTML, but gives in addition the possibility of defining new personal tags contrary to the HTML which presents an extremely rigid and present tagging set.

The automatic processing of course documents (v) is made possible by the XML associated parsers like XT of James Clarck , Xalan from Apache or others. The tagging language also allows, by the means of name spaces, the use of several vocabularies in the same document. We can, in particular, represent the tags corresponding to the course structure and the tags corresponding to rules of time precedence between the elements. The synchronization language SMIL (Synchronized Multimedia Integration Language) integrates in this manner into any XML document and thus a course. It conforms, itself, to the XML syntax. In SMART-Learning, the media elements could thus be sequenced and scenarized (viii).

Definition of course types

XML allows it using the DTD (Document Type Definition) concept which is a model which makes it possible to define a document class for SMART-Learning courses. Each document corresponds then to an instanciation of the DTD. Schemas are even more flexible than DTDs to define more rigorous documents types.

Separation between content and presentation

The great drawback of HTML is the mixing of the content and the presentation instructions (format, style) in the same document. These difficulties are overcome (vii) with XML and the associated tools. The structure and the contents of the document are described in an XML document whereas the

BEST COPY AVAILABLE

presentation is defined in an associated document which can be described with several style definition languages depending on the desired presentation. We currently use the first version of CSS. CSS2 will allow much more possibilities when it is recognized by the various browsers. These possibilities will be more increased with the even more complete language XSL:fo.

Current browsers visualize XML documents. However, not all of them recognize the whole set of the XML associated tools functions. It is however always possible to transform an XML file into HTML using XSLT by associating formats described in XML to it.

Course adaptability

The adaptation of the course according to the user profile is made possible using XSLT. It will first of all be necessary to adopt a structure defining the relation between the course and the profile as in the case of SMART-Learning.

XSLT can transform an XML document into another XML document according to present selection criteria. In SMART-Learning, these criteria (educational, of localization) can be associated to any element of the course (PS, PSe, media). Thus, a generic course, containing all the possibilities, will be transformed into a specific course thanks to an XSLT document which includes specificities of the learner profile (Fig. 3). In fact, the general transformation parameters contained in the generic XSLT document are transformed using the profile values.

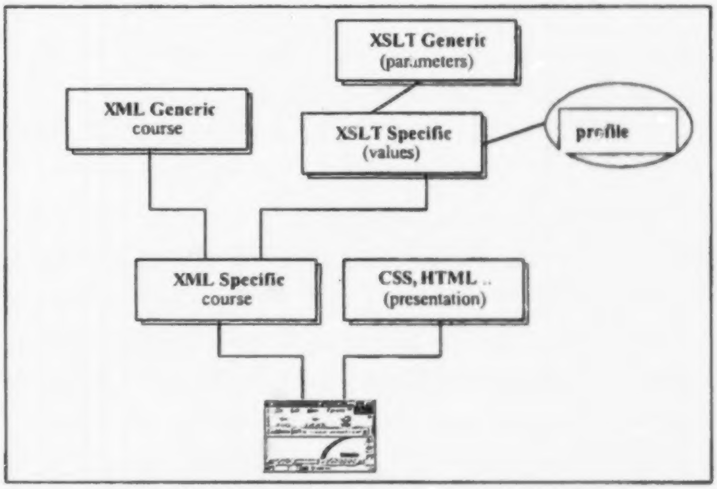

Figure 3: Successive transformations of a SMART-Learning course

Conclusion

XML and its tools allow thus, using a relatively simple representation, fitting the characteristics of a telelearning course and in particular the adaptative and structured courses of SMART-Learning

"TELEWEB" FOR DISTANCE LEARNING: THE EVOLUTION OF TELEVISED TEACHING INTO WEB COURSE

William M. Bercu
Distance Learning and Technology
Arizona State University
USA
bercu@asu.edu

Abstract: The delivery of distance learning has developed at a rate that corresponds with that of technology. This paper is an experiential account of the evolution of a televised course supplemented by the World Wide Web to a Web course supplemented by television. "Internet Skills for the Working Professional" is a course that uses the Internet to teach students how to use the Internet. This course was originally designed to be taught using television and face-to-face workshops and has developed into a primarily Internet-based course. This allows the participation of students outside the broadcast area. The level of participation, satisfaction and student learning and mastery of the essential material has in fact improved by using the Internet as the primary technology for this course.

Introduction

Arizona State University (ASU) has been delivering televised credit courses as part of its distance-learning program since 1955. Courses were originally broadcasted over a local commercial television channel. Televised courses are now delivered over a variety of different educational networks, campus based intranets, and local cable television. The medium for delivering distance education is evolving with the advance of new technologies. The U.S. Department of Education reported in 1995 that 75% of universities offering distance-learning courses planned to increase their use of computer technology and interactive teaching. Student enrollments for distance learning classes have increased substantially, as well (U.S. Department of Education; 1997). Many students enrolled in distance learning courses live within commuting distance of the university, but choose the convenience offered by distance learning. A major shift has occurred over the past five years in the technology used to deliver off-campus courses. With the increase of the Internet as a learning resource, student enrollments in web courses have dramatically overshadowed enrollments in televised courses. Table 1 compares student enrollments at Arizona State University in televised and web courses over six years.

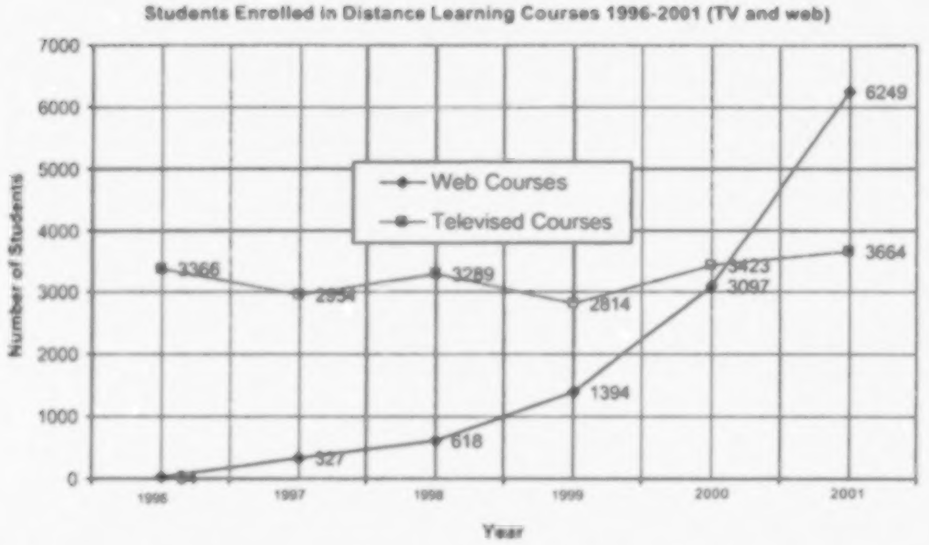

Table 1 : Comparison of distance learning enrollments in web and televised courses 1996-2001.

During fall semester, 1999, a televised Internet skills class was designed to provide students with a variety of skills using the web. This class was to be part of a program of study for a Master of Education Degree being offered on the Navajo Nation. Classes are conducted for two consecutive summer sessions on-site in the upper Northeastern corner of Arizona. Students complete 12 semester hours each summer and take web-based classes during the fall and winter semesters. One problem discovered in the early planning stage of the program was that many of the prospective students lacked basic Internet literacy skills. The face-to-face hours each summer session were oriented towards the M.Ed. content (teaching reading). Moreover, there was no computer lab space available at the site. To teach these basic Internet computing skills, students needed to actually see the different procedures demonstrated so they could master them on their own.

Developing a Tele-web Course

"Internet Skills for the Working Professional" was originally designed to use weekly, televised lessons that would normally be taught in a computer lab environment. Students, who live outside of the viewing area, purchase videotapes from the University's library system. These tapes are mailed the day of the prerecorded broadcast. The course, which is taught in a fifteen-week semester, uses the World Wide Web to provide materials, to foster student interaction, and to teach students how to use the World Wide Web. This course has evolved considerably during the nine semesters it has been taught. The purpose of this paper is to describe the design of this course and the major modifications that continue to provide a greater reliance on web delivery.

An advantage of designing and teaching a televised course is the ability to interview a number of different content authorities to supplement the instructor's presentations. Video taping and editing the interviews allows these "guest lecturers" to be reused in subsequent semesters. Examples include interviews with the three high-speed Internet service providers in Phoenix, Arizona: cable, direct microwave, and DSL. In another interview, teaching librarians gave presentations on searching the web and web resources. Each class session would have a different recorded interview or presentation, most of them taped at remote sites.

BEST COPY AVAILABLE

The Web portion of this course uses Blackboard course management products as well as custom designed web pages linked to the Blackboard site. A major feature of Blackboard that is used regularly is the discussion forum (asynchronous bulletin board). Students are tasked in some assignments to post responses to readings or projects. Forum postings are graded assignments. The five-stage model of computer-mediated conferencing is used as the weeks' progress. Students are expected at first to become familiar with posting to threaded discussions and assure that they overcome problems with accessing and navigating the website. Steps progress to online socialization, exchanging information, and creating an online learning community (Salmon; 2000)

In the original design, Internet Skills was taped on Tuesdays and broadcast on educational cable on the following Saturday. Out of town students received a copy of the videotape usually on the Friday before the broadcast. Immediately after the broadcast on Saturday morning, an on-line lab was held for one hour. The class used *Tutor-net*, Blackboard's synchronous chat tool, for these meetings.

During the second year offering this course (the third and fourth semesters) the "library" of guest speakers and content experts was increased by inviting guests to the broadcast studio in order to demonstrate different types of technology. A panel discussing the Arizona Department of Motor Vehicles online licensing program was hosted, as was a presentation on identity theft from a U.S. Postal Inspector. Recordings of these guest speakers further enhanced each broadcast topic.

The fifth rendition of this class, during Summer Session 2001, *Internet Skills* made its next evolutionary step by providing a live webcast for each session. Broadcasts were streamed to a RealSystem web server. The broadcast was simultaneously archived as a real media file and linked to the "lectures" section in the Blackboard course site. During this session, a student who returned home to Taiwan for the summer used RealPlayer in a cyber café to view the broadcast portion of the course. Broadcasts and archives are encoded in a "Multi-rate SureStream" format. (Real Networks 2002) This adjusts the stream of the broadcast to the dynamic conditions of the user's Internet connection. Webcasting continued through the following year.

During the next summer session, Internet Skills was only offered as a web class, with no broadcast television component. Webcast archives from previous semesters were edited into shorter pieces focusing only on the guest speakers. These clips were included throughout the web-based instruction and students used RealPlayer to view them. The instructor was able to devote more time developing interactivity in the course, by not having to present a broadcasted lesson each session. Student satisfaction and achievement were both extremely positive.

Planning for the Future

Currently, it is planned to broadcast the course one more time using the public educational cable channel. Added this semester will be a question and answer session for students who telephone the studio during taping and webcasting. Digitized media will be provided on a CD-ROM for introductory portions of this course in lieu of mailed videotapes for those students taking the course outside of the broadcast area.

This Internet skills class is gradually being tailored with its content and media to possibly facilitate publishing a DVD to accompany the web-based instruction. The experience of designing and teaching ten semesters of this course has corresponded with changing technologies, pedagogical trends, and student preferences to delivery. This distance-learning course, which was originally television based and supplemented by the web, has transformed into a web course, supplemented by (digitized) media.

Cases of Multimedia Applications to Enhance Learning

Ian Bertie
Universidad Católica de Chile

Introduction

At our university we had the usual Computer Center in the sixties with an IBM 1620, later with a Burroughs 3500, etc., and the use of computers done mainly by engineering and math students. The change of paradigm came in 1985 with the Macintosh's graphic interfase and the approval of a campus wide proyect to insert computer labs in all other areas, such as art, literature, social sciences, languages, etc.

In the late 80's we designed a plan to introduce teachers to the use of computer aids in their work, and devised a yearly contest of ideas where financing was won to be able to carry out those more promising ideas. Some interesting products came of these efforts. We produced a software developed for history students called "Tierra" (Land on sight!) regarding Columbus' discovery, and the following year were able to win the "Wheels for the Mind Contest" as best university in Latin America.

We produced the best Hypercard application for LA with "HyperEstática", to teach structures to architecture students.

MacWorld considered as Best International Entries in a Superstacks contest (a Canadian SW being the third entry) a couple of teaching software we produced: another history teaching aid (Revolution!) and a second SW for architects (Earthquake!)

Why these programs were succesfull as compared to the multiple other ones (about 200) we produced is a source of practical knowledge.

Some of the software we have produced can be seen the catalogue on
http://www.puc.cl/sw_educ/catalogo/index.html

Communication in the 80's was slow and dull compared with todays possibilities of multimedia material, such as comparing the telex machines to faxes.

At the time data communication networks came through another university, older and owned by the state. We decided to band together with other universities and become independent, creating the first ISP as there were no commercial providers of internet in the country at the time. When Internet service was taken up by the commercial sector later on, we sold out in order to concentrate on our specific mission in teaching and research and hired the service for ourselves.

We were the first university to provide e-mail and free internet access to all our students. We designed our university site and put information on the web for our students to see, and discovered to our surprise we were amongst the country's top ten sites as far as number of hits go.

A reduced number of teachers were enthusiastic about the Web, a large number stepped back and shrunk from HTML, FTP, ISP and such. And many of the enthusiatic ones wanted someone – not themselves- to paste the books they had written on the web.

So we produced a typical course website and easy to use tools to enable faculty to interact with the web, and here we are now, convincing faculty that a new teaching approach is needed – not just pasting the stuff they have.

We have designed a WebSite that has three areas:
Teaching Materials
Administrative Information
Communication aids.

I do not plan to go into detail of the typical website for a course at the Universidad Catolica since it can be easily appreciated at:
http://www.puc.cl/html/framecur.html

The issue I plan to analyze is the appropiateness of the material that can be put on the Web.

The possibitities of putting material on the web are varied. You can of course put reading material. Some consider that more of a way to distribute said material that a way to have people read it, since a number of users still prefer studying material in hardcopy than reading it on the screen. You can put presentation slides, which can be used for class and the students can review the same material later.

You can put video clips to be seen on demand. And you can produce a variety of didactical games students have to go through.

The idea is to take a quick, practical look at a simple checklist versus a determined software, to see if an adequate number of points are met to insure the appropiateness of the technology to the occasion or content.
The simple checklist will be set as evaluation parameter against examples taken from last academic year's production of software to be used as aid in teaching:

- Chilean Musical Activity in the XIX Century, by professor Carmen Peña, from the Music Institute, financed by the Teaching Devepoment Fund
- Chilean Seas, by professor Ana María Errázuriz, from the Geography Institute, financed by the Fundación del Mar.
- Virtual Catalogue of Professional Practices, by professor Rodrigo Tapia, from the School of Architecture, financed by the Teaching Devepoment Fund.
- Vital Cicle Care, by professor Patricia Masalán, from the Nursing School, , financed by the Teaching Devepoment Fund.
- Drug Prevention, by Carolina Méndez, ATEES Proyect, for local schools.
- Mathematics of Movement, by Jessica Puschel, ATEES Proyect, for local schools.
- Lets get to know the Mapuche Indian World, by Jessica Puschel, ATEES Proyect, for local schools.

These applications, and others from previous academic years production, can be found at The Catholic University of Chile Website (**www.puc.cl**) in Aids to Teaching, Software to Aid Teaching:

Apoyo Educacional
Software de Apoyo a la Docencia
http://www.puc.cl/html/frameswacad.html

Uses that are innappropiate for the new technologies, or even when they do not take full advange of that certain technology's potential, may end up making it seen rather banal.
This is specially so when the saying "there is no second chance for the first impression" applies. Non technical people who witness for the first time a demonstration of a new technology that fails, or proves unsatisfactory, do not necessarilly distinguish content from container, do not always differ the technology with the specific use it has been given. The tendency to be prejudiced against the technology developes, when the responsibily of that failure is in the mismatch of use versus the technology chosen.

The Simple 12 point Checklist

1. Intensity

The more senses involved in delivering the message makes it more intense, and gives it a better chance of being remembered by the different types of memories individuals have: drawings (better than a thousand words) for those with visual retentiveness, sound for those those with audio retentivenes, movement for those with kinestesik memory.

The earthquake SW had a brief introduction where some buidings moved and toppled and the cry Terremoto! was heard and read. Similar ocasions presented themselves within the SW for some key concepts, as when showing the effects of rigid buildings founded on rigid soils, etc.

2. Repetition

Repetition fixes knowledge to the neurones as we know from kindergarten and up. The trick is of course to have some repetition and some variability interwined, so as to avoid the dullness of plain repetition. One of the great advantages is that with hyperlinks you can use different roads to get to the same conclusion and reinforce it. The other possibility is to repeat the concepts but with variations in the depth in which the subject matter is covered.

In the Earthquake SW you could move through the whole SW at a simple introductory level to get a first overall view, go through it at an intermediate level for normal study content, or inmerse and analyze matters in depth by dicking on icons that contained more detail in some themes (similar to boxes in books or magazines). But in software you don´t have the distraction of on view boxes as you have in books, you don´t see them unless you choose to do so by clicking on an icon and making the boxes appear).

3. Attention.

Capturing the users attention and retaining it is no minor chore, starting with the need to give it a rememberable name. Give it a short simple name that catches the attention of those interested and that manages to conveys its contents.

If you fall into the temptation of naming your software with a long name in sake of accuracy name/content such as ..."Genetics of the degradation of lignite mediated by fungi" or..."Mecanisms of transcriptional activation of defense genes to stress in plants" (yes, they are the real names) and no one will be able to repeat it.

We had The use of Computer Aided Design as exemplified by its Applications on Classical Architecture of Palladio, and left that as a subtitle with simply "MacPalladio"

as rememberable one, which brought the Macintosh Computer to mind, and Apple´s funding to the institutional pocket.

4. Association.

Whenever possible, images that had the possibility to be known by the students are to be used. This also favours the idea of establishing association with things in real life.

We put this into practice when designing the Structural Basics software, when depicting buildings with different static loads according to their use: a photo of the actual classroom, a photo of the campus library for 600 kgs/sq.meter, etc

5 Affective links.

Whatever previous knowledge the student brings along may come in handy when trying to add new concepts by stablishing links from one to the other.

In both software programs to teach structures we had a character that explained some concepts (such as twisting a rod to show flexion in beams). A trio of characters was designed, and students were requested to choose the one they felt most identified with, which turned out to be a lanky, bearded, woolscarfed representation of a local architecture student.

6. Variety of Presentation Material.

Because of some unknown reason, some teachers think that because its all about transmitting their image across the ether, that makes it enough.

We try to diplomatically encourage teachers to use additional material. This is done at the meeting where the project is prepared: we ask the teacher **when and how** (and not if) he wants to time the introduction of the charts, video clips, models, etc, taking it as a matter of fact issue.

7. Clear Indexing

This rather obviuos item is inexplicably often forgotten. One can see the names Chapter 1, Chapter 2, etc., as if this gave any useful information.

The finding of the right page in a book is a must, to find the way to a needed file in the web is essential. This is specially so when the file must be opened to see its contents, and even more so in the case of large files. Some very good video libraries have been seen to have little use by professors and students in spite of the great material that has been collected. We think it is mainly due to the lack of the time needed to peruse through the tapes in search of the adequate material (by professors and students).

The disadvantage of the secuential media should be solved in the video on demand / streaming video solution by having short clips that are very easy to find, in indexes that should have names as obvious in conveying the contents of the clips as possible.

8. Simultaneity

When simultaneity is not possible in real life, or is very difficult, the computed aided resourse can be very valuable.

We all know the advantages of an animated model to explain how an internal combustion engine works, but there are instances when a moving model is more valuable still.

The vision of a cross section of a human heart in movement and the sound a certain cardiopathy makes on the stethoscope is only made possible by superimposing an animation and the recording of the sound., since the cross sectioned real heart will certainly not be moving!

9. Size scale different to normal

When size scale is different to normal (microscopic or macroscopic), the computed can replace or aid in preparing for the actual experience in the use of costly instruments.

The difficulty in giving access to an electronic microscope to a large number of students makes it desirable to make the most of such occassions. A round of previous practice on the computer makes the use of limited access equipment highly effective. This is also valid for telescopes and such, especially since the university's astronomical observatory is located rather far from the main city campuses.

10. The difficulty of access to some material.

Even if the materials for study are present, a large body of students wishing to gain acces to them is not easy to accomodate.We do not propose to substitute the real thing by replacing it with a computer image, but we have found that the previous knowledge of a simulation quickens the pace of the students time spent withthe real-difficult to access material.

Such is the case for the Aapgard test for babies, where no mother would want her child to be handled by a dozen nursing students, the vision through an electron microscope for pregrad students, the time spent with real corpses for anatomy students, etc.

11. The recording of scarce occasions.

Visual aids in motion are very valuable in quite a few instances. We evaluated and bought video on demand servers from Real and Apple. Similar to what happened with static graphic material to be put on the web, most faculty at first want to do the old things with the new resources. When a certain event is very unfrequent its register in video makes it more valuable.

Por example, video takes during an earthquake, a flood, the mating of an animal of one a year fertile period, an operation to separate siamese twins…

12. Time scale is different to normal.

A process can take much longer than the lapse of a semester, such as the growth of trees for the forest/lumber industry, or a process can be so quick as to be difficult to behold by the normal eye (MIT's high speed photography lab). In these instances the use of animation brings the process into the adequate time frame by accelerating it or freezing it, and permitting its repetition.

Promoting the Development of Students' Information Literacy Skills: Insights from the Postsecondary Classroom

Ty Binfet, Ph.D.
School of Education
Loyola Marymount University

Abstract: The principal aim of this pilot study was to explore the development of students' information literacy skills as they completed annotated bibliographies related to a topic in educational psychology. One challenge facing postsecondary educators is to encourage students to conduct comprehensive on-line searches of resources related to course assignments. Thirteen graduate students in educational psychology were asked to compile a web-based, annotated bibliography in lieu of writing a traditional term paper. Self and peer assessments were administered and revealed that students do not profess to have a search strategy in mind prior to starting their on-line research, that they do in fact develop strategies to streamline their search efforts, and that they report an increase in their comfort level using on-line databases as a result of having completed an annotated bibliography. Implications for postsecondary instruction and information literacy are discussed.

Introduction

"In today's information age, one has to be able to define information needs, formulate search strategies, access information, assess and interpret the information sources, and communicate a stance on a problem or hypothesis." (Herro, 2000, p. 555). One challenge facing postsecondary faculty is to encourage students to conduct comprehensive on-line searches of resources related to course assignments. Students completing research assignments have a tendency to consult resources that are convenient and easily accessible (Gutierrez, Wang, & Herring, 2001). In their haste to find esources related to their research topic, students often conduct compromised searches due to a variety of factors. These include: a lack of time (e.g., leaving the assignment to the last minute); unfamiliarity with how to efficiently use databases (e.g., on-line information databases such as EBSCOHOST, ERIC, and PYSCINFO); and/or a lack of understanding of the criteria required for selecting high quality publications (e.g., peer-reviewed journal articles).

With current trends of incorporating technology within classes, faculty are increasingly asking students to be "informationally literate" and to apply information literacy skills in order to complete course assignments. Information literacy has been described as having multiple dimensions. The components comprising information literacy are many and include: the creation and transmission of information; the construction and application of a search strategy; accessing information; the physical organization of information; and the evaluation of information (Kapitze, 2001).

Information literacy strives to enhance the student's ability to explore text-based communities and to forge connections between varied resources of information (Cope & Kalantzis, 2000). Kapitze (2001) argues that information literacy " . . . should not be the domain of the teacher librarian alone and that training in it should be integrated across all subject areas . . . " (p. 453). Indeed, frequently, faculty make assumptions as to the research abilities of students with respect to compiling information for class-related projects and assignments (Scott, Schaad, Mandel, Brock, & Kim, 2000). Leckie (1996) posits that "Faculty must assume more responsibility for teaching information-retrieval skills in their courses, . . ." (p. 201). Thus, in order for students to meet the demands of in-class assignments requiring extensive on-line searches, faculty must make efforts to support the acquisition and development of students' information literacy skills.

In an effort to encourage university students to develop their information literacy skills, students were asked to complete an annotated bibliography in lieu of writing a traditional term paper. The principal aim of this project was to explore the development of students' information literacy skills as they completed an annotated bibliography related to a topic in educational psychology. Specifically, this project strived to answer the following question: What aspects of students' information literacy skills are impacted by the completion of an on-line research assignment?

Method

Participants

A small sample of 13 students (3 males, 10 females, M = 23.5 years, SD = 1.97, 6 Caucasian, 3 Asian, 2 Hispanic, 1 African-American, and student of blended ethnicity) participated in this pilot study. All of the participants had completed 4-year undergraduate degrees and were seeking their teaching credential as part of their graduate training in education. Students received information in their course syllabus describing the web-based assignment and outlining the expectations for researching their chosen topics. Briefly, each student was asked to conduct an extensive on-line search of resources related to a topic in educational psychology (e.g., the impact of anorexia on academic achievement, the effects of same-gender schooling, recreational alcohol use and academic achievement, etc.). Over the course of a six-week, summer semester, students were asked to generate a list of references and resources related to their research topics. For each resource, students were asked to submit a 1-page written reflection that provided a summary of their chosen resource as well as information regarding how their resource helped them better understand their overall research question. Table 1 illustrates the nature and number of resources required.

Source	Expectation
Peer-Reviewed Journal Articles	4
Internet	2 URL's (+ description of pathway to target information)
Popular Periodical	1 resource (e.g., TIME, NEWSWEEK)
Newspapers	1 National News articles
Local Support Agencies	1 (e.g., Community-based resource groups)

Table 1: Nature and number of references to be included in web-based assignment.

Measures

Information Literacy Comfort Scale

Information regarding students' information literacy skills was assessed via three distinct sources. First, at the beginning of the semester and after informed consent had been obtained, students completed a pretest measure assessing their comfort level in applying information literacy skills in on-line academic searches (e.g., "I have a hard time telling the difference between poor quality and high quality web-based resources", "I know tricks or tips that save me time when researching web-based resources"). This scale consisted of 10 items that required rating on a five point Likert scale (1 = True, 2 = Somewhat True, 3 = Neither True nor False, 4 = Somewhat False, 5 = False). At the end of the semester, students were asked to complete the same measure again (i.e., the post-test).

Self-Evaluation of Information Literacy Skills

This measure was comprised of 11 items that required both a rating (i.e., Strongly Agree through to Strongly Disagree) and open-ended responses (e.g., "Three tips I have learned from researching resources on the internet are: ", "After having completed this project, what have you learned about differentiating a high quality internet-based resource (i.e., something you would include in your project) from a poor quality resource (i.e., something you would not include in your project)?"

Peer Interview

Insights into students' information literacy skills was gleaned from a peer-based interview comprised of three questions (i.e., "What is information literacy? What does it mean to be *informationally literate*?", "To what extent are you convinced your partner answered his/her research question in compiling his/her annotated bibliography?", "What has your partner learned about researching internet-based resources after having completed this project?").

1244

Results

Recall that information regarding students' competency with information literacy was collected via self-assessments of students' comfort in applying information literacy skills, open-ended questions regarding students' information literacy skills, and peer interviews aimed at exploring students' knowledge regarding on-line searches.

Information Literacy Comfort Scale

From pre- to post-test, after having completed their annotated bibliography, five of the 13 participants reported feeling more comfortable conducting on-line research-based searches. When asked whether or not they had a search strategy in mind before beginning their research, the majority of students (i.e., 11 of 13) responded that they did not. Last, after having completed their research project, the majority of students (i.e., 9 of 13) reported that they were better able to discern high from poor quality on-line resources. Table 2 illustrates pre- to post differences in self-assessments for 9 of the items used in the Comfort Scale.

Variable	n	Pre-test M	Post-test M
Comfortable researching academic-related sources	13	2.12	1.35
Able to explain the concept of Information Literacy	13	3.69	2.19
Able to research internet-based academic sources quickly	13	2.50	1.58
Uncomfortable using internet to research academic projects	13	4.04	4.23
Hard time telling difference between poor & high quality web sources	13	3.08	3.65
Know difference between peer-refereed article & popular periodical	13	2.23	1.42
Have favorite database used when researching academic articles	13	2.96	2.19
Know tricks to save time when using internet-based resources	13	2.96	1.85
Have strategy in mind before starting research on a new topic	13	2.73	2.23

1 = True, 2 = Somewhat True, 3 = Neither True nor False, 4 = Somewhat False, 5 = False

Table 2: Mean scores on self-ratings on the information literacy comfort scale.

Students' Self Evaluation

Several themes emerged across the responses generated by the participants' self-assessments of their information literacy skills. First, when asked to identify tips for researching internet-based resources, students remarked that one must be efficient in differentiating high from poor quality resources. As one student wrote, "You must find more than you need. The closer you read, the less (fewer) resources you'll find that actually fit your research question." Several students remarked that resources were easy to find but that one needed to be critical in selecting resources (" . . . there is a lot of stuff which is easy to find, but one needs to be critical of sources; look for accountability and where the authors get their information."). In an effort to discern credible (or high quality) resources from internet "junk," (i.e., resources not directly related to one's research topic) students additionally suggested looking at within-text referencing and the bibliographies of individual resources. That is, were the resources well substantiated within current research findings? Last, students raised the issue that wading through large amounts of unworthy resources can diminish one's ability to think critically about the resources one is evaluating. One suggestion to reduce having to sift through unwanted resources was to both use efficient terminology to eliminate finding unrelated resources and to conduct advanced searches (e.g., limiting one's search to "peer-reviewed publications", etc.).

Peer Interviews

It was hoped that the peer-led discussions regarding information literacy would possibly uncover aspects of on-line researching that had not been captured on the paper and pencil questionnaires. Some of the prevalent themes in the students' responses revealed interesting findings regarding how to conduct on-line searches. For example, students reported to their peers that "you must be flexible in using a variety of key words to find information", "there are a lot of unacceptable resources – it takes time to sort out the non-credible ones", and that "different search engines provide different information". Certainly, one common theme among the peer-based responses was the notion that there is a great deal of on-line "junk" that must be sifted through in order to find credible and useful resources. The task of sifting through undesirable resources proved problematic for a number of the participants. In fact, several students admitted to being tempted to change their research topic to fit the resources they found rather than remaining true to their original research question.

Discussion

Recall that the aim of this study was to explore the development and use of information literacy skills by university students as part of a research project exploring topics in educational psychology. Overall, it appears that having students complete extensive, on-line searches of academic topics combined with written reflections contributes to the development of students' information literacy skills all the while supporting their understanding of key course-related topics. That is, through the researching of on-line resources related to topics in educational psychology, students honed their web-based research skills and developed techniques for maximizing their research efforts. For example, students responded that using efficient terminology was key to conducting successful searches and that one's choice of database maximizes one's chances of accessing desired resources. Certainly, in their attempts to discern high from poor quality resources, students were exposed to, and gained, expertise in their chosen topic. This was evident by the complexity of students' written reflections and their demonstration of knowledge related to their selected topic area. Surprisingly, students reported not having a search strategy in mind prior to conducting on-line searches. It appears that students do indeed have ingrained or habitual on-line search strategies in mind when conducting web-based searches. Perhaps, given the high number of searches that students conduct, they are unaware of the steps they may take to render their searches more efficient. Last, responses to peer interviews revealed that even with attempts to streamline their searches, students were faced with the task of having to wade through large quantities of resources unrelated to their area of research. Students commented that the task of identifying key resources was labor-intensive and compromised one's ability to think critically about the information students were seeking.

Kapitze (2001) argues that information literacy requires individuals to construct and apply a research strategy, access a variety of information, and evaluate the quality of the information found. Clearly, as evidenced by the comments and insights offered by the participants in this pilot study, information literacy may be promoted concurrently alongside the research agendas of post-secondary educators. That is, by encouraging students to conduct informed on-line searches as part of regular class assignments, educators can assist students in developing information literacy skills that ultimately contribute to the development of streamlined search strategies, increased abilities to discern high from low quality resources, and increased comfort levels regarding web-based searches.

Taste the difference.
Training and optimizing of synchronous, audiovisual, cooperative telelearning.

Thomas Bliesener

You get a full understanding of many things only when you are able to explain them to others. If you are able to do so even within a teleconference, you have a skill that is highly appreciated in many jobs. Both facts are reasons for the Department of Communication Science at the University of Essen to offer courses for training in teleconferencing. The Federal Minister for Education and Research provides the funding to this project. Supported by trained tutors, groups of three or four students can learn, rehearse and apply synchronous audiovisual teleconferences, using their home computers and telephones, in order to prepare for examinations or to collectively produce documents such as texts, webpages, flash animations or powerpoint presentations including images, sounds and videofiles.

Participants are required to dispose of internet connections with ISDN (2x64k) or DSL, which is the case with a total of 40% and 10% of all students. With ISDN, one line is used for a connection to the internet service provider, carrying a netmeeting data only conference, while the other line is used for a telephone conference by conventional telephone devices or alternatively by the video telephony software Alice, the ISDN card *Fritzcard* and an ISDN based multipoint control unit (MCU). With DSL, netmeeting is used for an audio video data conference by an IP based MCU with an upstream of 110k and a downstream of 440k. In order to avoid incompatibilities among the computers and to minimize efforts for configurations, a master laptop was optimized, and clones of it are borrowed to the trainees.

Every course comprises 15 participants and 5 tutors. The required knowhow is learned and trained on the campus within two days. In the month after, the small groups perform three or four teleconferences of about three hours each to solve their tasks.

Subjects of the first two training days are:

- Hardware, audiovisual add-ons, drivers, conference software, ISPs, MCUs, telephone services, ISDN protocoll, IP networks, DSL formats
- The social organization of synchronous cooperation on identical documents
- Dealing with the differences of monitor and sound display at the different locations of the participants

Differences between locations play an important role in most synchronous telelearnings, and despite the progress in data transfer technologies, they will do so for the next couple of years. That's why this article is devoted to them. Since differences between locations cannot be revealed sufficiently only by *learning by doing*, particular excercises and methods are needed in order to train a better feeling for them and an optimized dealing with them.

1. Exercise: Effects of media on focusing on targets
   Participants can do an exercise borrowed from the didactic of the fraction of light: They are to through darts on a dartboard under water. After a couple of attempts they will intuitively take into account the factor of fraction and compensate it when aiming at the target. Trainees can transfer this experience to addressing remote conference partners via technical media. Alternatively, this exercise can be done with one of the numerous java applets on this subject.

2. Exercise: Rhythm and timing in human communication
   Participants can be given small rhythm instruments and be told to contact each other solely by the use of them. Thus they develop a feeling for a common rhythm and for the power of delays to disturb it. They can transfer this experience to verbal dialogs and their interaction with listener signals. Alternatively, this exercise can be accomplished with a keyboard software as delivered together with many soundcards.

3. Variations and verbalizations in teleconferences
   At the beginning of a teleconference, participants can use their cameras and microphones to make

tours around their workplaces and their own bodies. Thus their partners get a broader basis from which they can infer on the actual relations at the remote location. Moreover, in the course of the conference, participants can describe verbally their perceptions and intentions, and they can announce actions, the consequences of which become perceivable to their partners, e.g. minimizing a window during desktop sharing.

4. Marks and signals in teleconferences
   Many actions on input and output devices are not visible, audible or knowable to conference partners, but can be communicated by explicit signals. E.g. the movements of the mousecursor can be slowed down, the mousecursor can be magnified, and a flag can be attached to it. Similarly, to every click you can attach the display of a colored circle around the mousecursor and a sound on the partner's computer.

5. Additional capturing
   Sights of your workplace, which normally stay invisible to your partners, e.g. the keyboard or the illumination source, can be captured with a second camera. By displaying this capture on your own desktop and sharing your desktop with your partner (not replacing the first video, as it would be done with a document cam!), he can permanently monitor it and mentally combine the two videos to one differentiated model of your location.

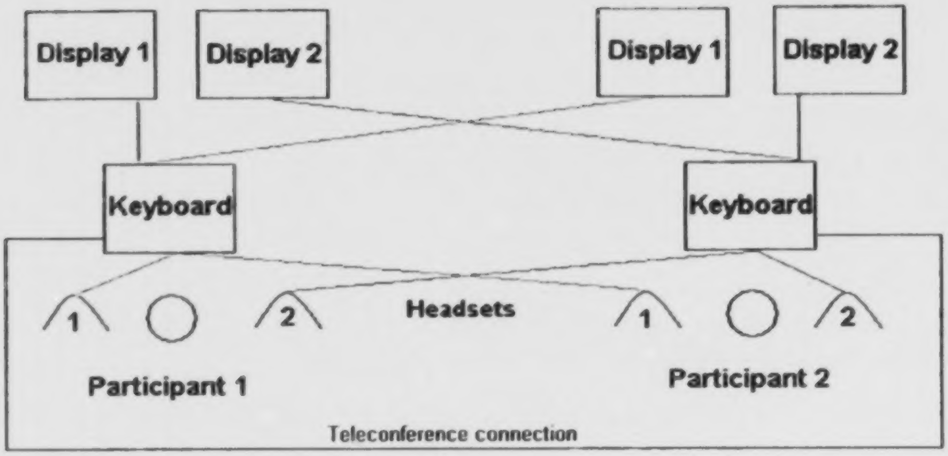
6. Echoing and desktop sharing
   You can also use built-in possibilities of teleconferences for simultaneously sending your partner a feedback of how he is seen and heard. By desktop sharing, he can see his remote video, and by displaying his voice via boxes and re-recording it via microphone, he can hear his remote voice. Neither of these feedbacks, however, represent the true quality and timing at the remote location, since on their way back, they undergo additional losses and delays. So they mislead to an exaggerated impression of the distortions.

7. Exchange of recordings
   You can avoid the exaggeration of distortions by making loss-free capturings, e.g. screenshots with Snag-it and screenclips with Camtasia. Then you transfer the files to your partner, which is a loss-free procedure, too. The disadvantage of this method is its asynchonicity. When the recording arrives, the episode is over. So your partner can relate the recording of the remote side of the episode only to his *memory* of its local side.

8. Syntopical monitoring
   A *realtime and lossfree feedback* can be given this way: You install two computers with cameras etc. for teleconferencing within the same physical room and connect them in the usual way of teleconferencing, e.g. by telephone conference and by netmeeting via ISP 64k. Additionally you supply each computer with a second headset and a second display (or a beamer projection) directly from the other computer. So the two participants simultaneously receive the local and the remote audio and desktop displays in the original timing and qualities - an unbeatably realistic experience of a teleconference as a whole.

   Some precautions, however, are advisable:

   - One's own voice plus a delayed echo cannot be listened to for a long time. For extended acoustical explorations in this setting, you better use neutral live sounds, sound files or CD-rom.
   - One's own desktop plus its shared copy can be monitored only by comparisons which need extra time and effort, so the teleconference must be slowed down.
   - In case an auditory is included, who normally see little of the participants' actions, the teleconference must be slowed down and verbalized. Moreover, it may be better to display a beamer or multiplexer projection in a separated room.



Syntopical monitoring has the advantage that you only need half the number of training rooms, though your need for additional headsets and displays or beamers increases. If equipment is lacking, you can use one setting for syntopical monitoring for many couples of trainees one after the other. Another advantage is that the use of a common physical room encourages the trainees to test application sharing even with objects that tend to disrupt a netmeeting audio connection, especially audio and video files.

Syntopical monitoring is the only setting that allows participants to develop a realistic sense for the relationship between local and remote. After a few hours of training, they can apply their acquired intuition to regular teleconferences – as far as the same conference technology, ISP and MCU is used. For different settings with different distortions and delays, a follow-up training with syntopical monitoring is recommendable. There may arise a problem for participants who live far away and cannot easily come back for a second training. For them, you can show videoclips of a syntopical monitoring recorded under their new conditions. Alternatively, you only do trainings with technological conditions that are agreed upon to be used in later applications.

The courses for students in Essen are done with syntopical monitoring under the lowtech conditions of home learners. Nevertheless, the equipment for doing and recording sessions under an array of different hightech conditions is being installed for other target groups such as telelecturers, professional staff and media consultants. Should you want to get a closer view on a training session in our lab, you are welcome to become an observer – by teleconference.

Abstract: This brief paper overviews and synthesizes the eLearning aspects that are related to an Italian work-in-progress project (CSCLK) on knowledge management methodologies and tools for public administrations providing in eGovernment services. The project goal is to obtain a deeper understanding of problems which have prevented knowledge management from spreading among public administrations, and to identify main research tasks, major players involved, and most suitable implementation mechanism needed to determine the best solutions for these problems. Moreover, CSCLK aims at the development of a coherent methodological, organisational and architectural approach to support effective knowledge management environments to facilitate public administrations in the design and deployment of e-services to citizens and enterprises.

Introduction

In the last decade, the working procedures of complex organisations were significantly relying on their information systems. In particular, the quality of the databases and the performance of the communication infrastructure appear to be key enablers for successful enterprises. Organisations are continuously evolving and there is a significant shift of importance from information-based systems, mainly dedicated to the management of operational data, towards new systems that are based on more aggregated information (e.g., data warehousing), and knowledge (e.g., business process models), necessary for monitoring and controlling business processes and for strategic decision making.

After the first evolution from function-oriented to process-oriented business models, typical of the '90s, in this decade one of the most significant trend is the evolution from process-oriented to knowledge-oriented models. One of the main characteristics of this approach refers to the so-called "learning organisation" [Senge, 1990], this implies that working processes are not defined "a priori" (like in a traditional workflow), but are dynamically shaped as required by the environment (i.e., the services and products requested by clients or citizens, the available technology, the financial situation and so on). Similarly, the organisation must evolve, to rapidly and effectively react to a continuously changing scenario. In essence, the KM (knowledge management) is a key approach for new organisational models, that have to be: learning, adaptive, and therefore knowledge-based. The management of knowledge implies the enhancement of learning and performance in organisations through processes and practices of creating, acquiring, sharing and using knowledge irrespective of where it resides [Scarbrough et al., 1999]

The PAs (Public Administrations) can be considered as huge knowledge firms since they collect and process data and knowledge about citizens, companies and also PAs themselves. So, PAs need to apply KM strategies and to use IT support to exploit their intellectual resources more efficiently. This knowledge has different shapes and characteristics, examples are: on private citizens and companies, on the environment, on the social welfare, on politics and strategies, on judicial decisions, on practices, etc.

This brief paper discusses the issue of knowledge management in PAs and focuses on the problems which have prevented KM from spreading among Italian PAs. The following section introduces the methodologies used in the CSCLK (Computer supported Cooperative Learning and Knowing: methodologies and tools for knowledge creation and sharing in Public Administrations) project to identify main research tasks, major players involved, and most suitable implementation mechanism needed to determine the best solutions to introduce KM approaches in the public sector. Section 3 concerns the preliminary and expected results of the running project and its main research guidelines. Open problems and possible further evolution of the project are finally discussed.

Knowledge Management in Public Administrations

The term knowledge management is used to refer a broad collection of organisational practices related to generating, capturing, disseminating know-how and promoting knowledge sharing within an organisational, and with the outside world, including: organisational arrangements, personnel development, transfer competencies, and managerial changes and incentives to staff to share knowledge [OECD, 2000].

Public administrations are undergoing important Business Process Reengineering (BPR) as a result of eGovernment projects such as large provision of sophistical Web services to citizens. The most important dimension of change in the new concept of public service involves: (i) the breaking down of barriers between departments and units; (ii) the negotiation and implementation of multi-disciplinary and multi-agency networks and protocols: (iii) a more efficient and effective communication, transaction and co-ordination.

This state of affairs is accompanying the deployment of eGovernment projects for over a decade and it is pervasive: the transformation activity will create analogous problems to managers and personnel throughout the different levels of the public organisations.

The Italian eGovernment Action Plan was approved on June 2000, together with the launch of the eEurope 2002 initiative. The Plan is just entered into the operational stage with the evaluation of the first call of proposals addressed to regional and local administrations. The emphasis of the eGovernment plan is on the development of a public administrations' unified network in which knowledge and information could easily flow, and on the education processes to improve IT competence in the public sector. To reach this objectives, Italian Public Administrations have to start a difficult and exacting re-organisational process in order to change their bureaucratic structure. As a survey on the introduction of knowledge management in Italian public sector points out [RSO, 2001], public administration is an organisation in which there is an intensive exchange of knowledge because all its main processes need knowledge creation, acquisition, sharing and transmission. *Moreover, one of aim of the eGovernment plan is to promote an organisational structure that could facilitate the cooperation (and hence the flow of knowledge and information) between central and local administrations.*

Knowledge Management ideas, methods and tools, together with the conceptual and empirical framework of Communities Of Practice (COP) have a high potential to assist public administration in these eGovernment BPR processes. Some of the most urgent needs are, for example:

- *to secure the availability of knowledge on the introduction, experiences and decisions made when IT (e.g. ERP systems such as SAP) is introduced within a department or organisation;*
- *to extract and exploit the latent knowledge in (electronic) administrative files and records in an appropriate manner;*
- *to support the decision-making and consultancy service of civil servants at the front-desk or public counter with an adequate knowledge base on former cases, judicial decrees, etc.*

However, the attempts to experiment and implement KM based organisational models and information systems in the public domain are still in their early phases, although with different levels of development in the various countries.

Knowledge management can be considered as an industrial process, were knowledge is acquired, stored, processed and distributed to clients along a "knowledge value chain". In this perspective, we have to consider in the first phase the acquisition of the preliminary forms of knowledge (something similar to row material logistics, in traditional manufacturing). Knowledge acquisition is a core learning activity, it greatly varies depending on the kind of knowledge contents considered, and its source (i.e., where it originates from). Learning activities are becoming more and more important in both private and public sector, and knowledge extraction is the first step of its life cycle. CSCLK project focuses on this phase in order to better understand what are the best practices and the possible tools for capturing knowledge and to share and disseminate it. On the other side, before entering into this phase, it would be useful to analyze the strategies of the public administrations, in order to understand what are their priorities, main objectives, and customer requests.

One of the issues on learning organisations, that recently has risen much attention, concerns the informal knowledge that arises from the activities of experts in their fields. It is often difficult to make this kind of knowledge explicit and organise it effectively; knowledge creation process among people develops itself as spiral between creation of tacit knowledge and its transformation into explicit knowledge [Nonaka and Takeuchi, 1995]. There are several proposals in the literature to address this problem by empirical methods to collect knowledge at the source, in its preliminary form (tacit knowledge), and to support its evolution through more organised formats, until it becomes explicit and sharable.

The challenge for public administrators is to find a successful way of re-engineering, managing, distributing and, in one word, improving the administration knowledge. Many obstacles hinder this development: a first classes of them derives from the fact that all KM methodologies, tools and practices have been developed in (and for) the business community, hence their application to the public sector need a deep re-thinking and adaptation work. On the other hand, the general PA culture, although with significant differences from country to country, is rather conservative, and the adoption of a more open and collaborative way of working is often seen as a threat rather than as an opportunity.

CSCLK project

The CSCLK project is running in cooperation with Italian research centres and a group of business schools, and it is also involving some public administrations interested in implementing knowledge based management systems in their organisation.

The aim of CSCLK is to characterize the relationships between various knowledge needs and technological options in the on-going BPR processes in public administration as a result of eGovernment projects. This research is developing and experimenting a coherent approach and methodology for the introduction of effective KM practices and systems in Italian PAs, in different sites and sectors.

CSCLK is investigating the opportunities and the limitations of ICT support for the KM in Italian PAs. This project is based on a state of the art assessment obtained through desk research complemented with the experience and in this area within the consortium: it starts with a definition of the scope of the research, and an initial mapping of the main issues (inter alia, PA needs in terms of KM, best practices, on-going R&D projects, methodologies and tools, technologies and so on). Particular attention is given to analysing the issue of business orientation vs public needs for the existing methods, tools and practices. This "roadmap", that is under development, will address not only research tasks, but also a first indication of the major actors and of the instruments to be put in place for implementation. This is accomplished by reviewing four different sectors encountered so far in the real-world: knowledge as an *object*, knowledge as an *interpretation*, knowledge as a *process* , knowledge as a *relationship*. Based on these four knowledge discourses, there exists different types of ICT functionality and tools inspired by these perspectives on the management of knowledge [Sorensen and Kakihara, 2002].

Another important expected achievement is the creation of a first group of relevant actors representing the initial kernel of a wider community of users, suppliers, consultants and academia: the creation of such a community appears essential to generate the critical mass of expertise needed to agree on rules and common standards, and to ensure an effective take-up and spreading of KM in public administrations. In this phase the project also takes advantage of the cooperation with a European group of stakeholders and actors deeply involved in the deployment of KM in the public sector (e.g. a central government organisation managing the innovation strategies, a Federal and local government organisations).

Moreover, CSCLK consortium will investigate the current and future learning needs in Italian public administration, and it will analyse the most suitable methodologies and tools in implementing knowledge sharing. In this research phase, the project will consider both explicit and tacit knowledge management process. In order to sharing explicit knowledge, we will focus on the peculiarities in designing, building and managing courses in the public context. Particular attention will be given to the reusable learning objects (RLOs) strategy as an innovative approach to develop flexible and modular courses available also by Web (Uskov, 2002). The modularity of the reusable learning objects could be very useful in an organisation, like Italian public administration, that is shifting its organisational structure towards a network model. In such kind of organisation (also characterised by a local and central dimension), it is necessary to guarantee a continuous learning process in which every node could autonomously create its learning path according to its formative needs. As Longmire (2000) suggests, "with the appropriate tagging and knowledge management methodologies and tools, RLO strategy can reduce time spent researching and accessing content, thus facilitating rapid creation of new electronic learning content". RLO approach is characterised by an high flexibility, since the modularity (granularity) of the learning sequences guarantees an easily reuse of the material. Moreover modular learning objects facilitate a just in time approach to the customisation of the content through the recombination of the material at the level of granularity desired. Also searching and management processes of content are simplified by filtering and selecting only the relevant content for a single user through the use of the metadata tags. This approach is also useful because ensures that the design, development and presentation of the courses are consistent across the organisation, both at the central and local administrations level. This last issue is very important in the public administrations context characterised by its enormous organisational size and a lot of different departments and offices often dispersed geographically.

Finally the research activity is addressing Policy implications and implementation mechanisms. In fact, it is felt that proper amount of resources should be allocated to analysing how public administrations can coordinate their efforts in order to harmonise both the national and international policies regarding the implementation of Knowledge Management and eGovernment projects, and which funding schemes and opportunities could be exploited to this end.

Discussion

In this brief paper we introduced problems and technological options for supporting the knowledge based management for public administrations and we analysed the main characteristics of CSCLK running project in which research players aim to provide a contribution to the following domains:

- focusing on the main phase of the knowledge life-cycle: the learning phase;
- analyzing learning organisations: companies (or PAs) that are able to interact with their environment dynamically, running processes to create, capture, store and manage knowledge;

- obtaining a deeper understanding of the problems which have prevented KM from spreading out in Italian and European public administrations;
- investigating and characterize existing methodological and technological options for supporting the management of knowledge in PA;
- identifying those priority research tasks which will have to be performed in order to address the solutions of knowledge management implementation in PAs;
- identifying the major (public and private) players involved;
- analysing the most suited implementation mechanisms;
- developing a methodological and architectural framework for assessing and describing the role of knowledge management in PA involved in the design and deployment of eGovernment services;
- embodying the experience gained in a set of project wide deliverables which may be adapted for use in an extended range of administration contexts and stages of eGovernment maturity as well as in a set of local deliverables in support of ongoing programmes of development of eGovernment services;
- comparing the networks among PAs with the virtual organisation paradigm, focusing on how virtual organisations can configure themselves to effectively and efficiently manage the knowledge flows they enable [Barbini, and all, 2002].

Component-based Content Development for E-Learning Systems

Andreas Bollin, Roland T. Mittermeir, Roland Wohlfahrt

{andi, roland, rolze}@isys.uni-klu.ac.at

Abstract: Based on modularisation approaches for easy reuse and adaptation we developed linkage structures between e-learning modules that allow for the dynamic adaptation of presentations to interest- and knowledge profiles of individual learners.
The realization of these ideas is possible by extending LOM-metadata by "standardized" descriptions of the respective LOM's content and the preconditions presumed from learners.
These descriptions can play the role of dynamic link attributes.

1. Motivation

Following the definitions of Rosenberg (Rosenberg, 2001), e-learning refers to the use of internet technologies to deliver a broad array of solutions to support self-directed, open and distance education. But e-learning is more than delivering available content by technical media, it also encompasses new didactical concepts. After the first hype in the mid 1990s it became clear, that the requirements of e-learning systems (exchangeable and reusable learning units, system independent courses) cannot be achieved by just using hyperlink-technology. Various companies and organisations engage in the development of standards and concepts to assure that e-learning resources will be identified easily, are reusable and portable among different platforms. While component reuse is state of the art in software development, it is still a dream of course-authors to write content only once and to reuse it wherever and whenever needed. To support this kind of modularisation, standards (cf. SCORM or LOM, see http://www.adlnet.org and http://ltsc.ieee.org/wg12) are evolving. The general goal is to generate basic learning items (also called e-learning objects, shareable content units, or simply components) that are interoperable, reusable, durable, extendable and, manageable.

The next chapter introduces the concept of hard- and soft-links for supporting content reuse. Chapter 3 describes the basic steps necessary to implement hard- and soft-links and to integrate them in existing platforms. It concludes with an example of how to use the concept for generating a course and how the learner can benefit from the flexibility of the connected chunks.

2. Hard- and soft-links

The basic idea behind this concept is to support the reuse of existing learning components. To do so, we modularise the content of courses into components that can be recombined by future course-authors. The elementary components, referred to as content chunks, are kept with their metadata in a repository. They can be combined to higher level entities, modules, which form eventually the content of the whole course.

This goal is achieved by embedding content kept in a repository (content chunks) in metadata as shown in Fig. 1. The *general metadata* follows the LOM standard and positions the content in a general classification framework. *Pre-conditions* and *post-conditions* describe the learners assumed knowledge before and after studying this component. Finally, a *link section* relates it to other assets in the repository. This link section contains also links relating assets to form higher level entities (modules). The distinction between these link types is seen as a response to the criticism raised in (Seeberg et. al, 2000).

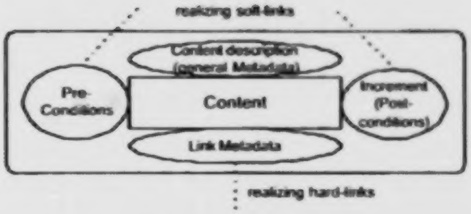

Figure 1: Metadata is attached to the content in order to enable hard-, and soft-link facilities.

Aggregations of chunks or modules leading to fixed sequences of presented material are realized by a type of hard-links we call *directed-link*. This type of link is to be provided by the author when creating a course (or when creating a germane set of learning components). It forces the learning system to provide chunk A (the source of the directed link) before chunk B (its destination). The second type of hard-link is called *r-link* (for relational link) and it describes the following types of relationships: "optional", specifying, that another chunk contains optional information: "special", stating that another chunk provides information in more detail; "general", leading to a chunk that contains a much broader information about the same topic; and "learner type", leading to a chunk containing the same information that is provided for a different type of user. The primary purpose or r-links is to support authors and to structure the repository.

To allow dynamic adaptation of e-learning content during the execution of a course, a user profile has to be taken into consideration. The key-idea is to supply the course in general with more material than the average learner wants to consume or with material presented on different levels. The dynamically updated interest- and knowledge profile of the learner is then used to select the appropriate chunk out of a pool of chunks based on the chunks' pre- and post-conditions. The knowledge necessary to understand a specific chunk has to be described in its pre-condition. The newly gained knowledge is described in a section called increment (or post-condition). Pre- and post-condition tags express implicit connections between matching chunks. Therefore, we call them *soft-links*.

Besides dynamic linking, pre- and post-conditions support course authors. During course-creation, the connections (directed hard-links) between chunks can be checked for feasibility. Pre- and post-condition tags of succeeding components must be compatible and authors could be warned, if the "knowledge distance" between learning components is too large. During repository maintenance, pre-/post-conditions can be used to support consistent definition of r-links.

3. Profiles and pre-conditions for dynamic generation of e-learning content

The previous section explained the concepts needed for dynamically generating user-specific e-learning courses. Here, we show how these concepts can be realized from both, the learner's and the system's perspective. In order to do so, we have to consider first a usage scenario: Let's assume a learner is interested in how to cope with elearning content management. In a heterogeneous group of learners, some might want a general introduction and progress in a systematic manner. Others have specific questions and want just an answer to them. Fig. 2 shows a map through the landscape of e-learning content available for any of these learners.

It is obvious that the content exhibited in Fig. 2 can be perused via different paths. However, it cannot be meaningfully studied in random order. Hence, the course author is challenged to provide sequences of chunks (learning strings) that are to be studied linearly, but can be combined in multiple ways. Students can use different entry points to this content. To satisfy these constraints dynamically, learners cannot be confronted with the raw chunks of e-learning content. These chunks or modules have to be rather embedded in an environment, that allows to assess a user profile and to update it along the users learning path. This embedding is sketched in Fig. 2 by the entry "Course-Portal". It serves to tell the system the users learning aspirations as well as the knowledge, the s/he has already acquired beforehand. In the case of our example, this information can be obtained by offering the student in addition to the main entry ("Introduction to Content Management") also two side entries ("Meta-Data", "Updates of Web-Material"). The individual topics (modules) consist of chunks connected by the course-author using directed-links. Hence, the internal modularisation of these entries remains hidden from the learner. The arrows shown in Fig. 2, represent soft-links. I.e. they exhibit

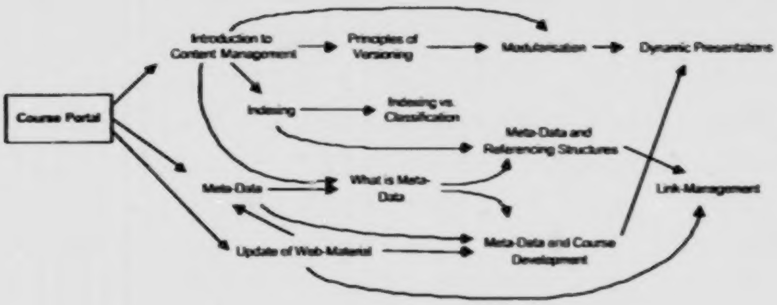

Figure 2: Content structure and relationships between content chunks in a course on Content M anagement

dependencies seen by the author of the course and thus they are dependencies implicitly expressed in the pre-/post-condition embedding of the individual modules.

As pre- and post-conditions specify the learners knowledge in relation to the given module, the knowledge increment provided by the module can be computed as the difference between pre- and post-condition. Basically, for each chunk, this increment can be expressed by a single attribute. Hence, for a complete module or learning-string, it will be a list of attributes. Since many chunks will not start from scratch but rather expand on an issue, the progression of knowledge in a certain domain can be indicated on an n-point scale. (The current implementation uses n = 10). Consequently, the user-profile and the pre-/post-condition structure have to be expressed in the same language. Propositional calculus (with fuzzy logic extensions) serves this purpose. Under these assumptions we have the following rules: *PostCond* := *PreCond* ⊗ *Inc* (with ⊗ representing conjunction of the pre-condition with the module's increment such that higher numeric values in the increment override lower numeric attributes in the pre-condition). Likewise, the choice of candidate modules made available to the learner at a given point is initially the portal only. After the questions of the portal have been satisfied, all modules with pre-conditions weaker than the positive user-profile obtained from the interaction with the portal are furnished in the candidate set of modules offered for study at this point. Preference is given to those modules, where the profile contains a negated term that figures positively in the modules increment or where a positive increment in the degree of knowledge can be identified. Thus, one has basically: *Profile* ⇒ *PreCond*.

It should be noted that the modules profile is mainly determined by the pre-conditions of the individual head-chunks of learning strings. As the learner decides for one of these candidate strings, the learners profile is updated in a piecemeal manner by the knowledge increments of the individual chunks studied by the learner. Within a module, the individual content chunks are hard-linked in a linear manner. When a given topic has been covered in such a way, the learner is offered a new chance to decide. Thus, after perusing the "Introduction" s/he might keep on going to "Principles of Versioning", or directly to "Modularisation", as well as to "Indexing" or to "What is Meta-Data". However, if the learner uses rather the problem-oriented entry of "Updates of Web-Material" s/he can next learn about "Meta-Data" or, if s/he indicated in the profile (or at this point) that s/he is conversant about metadata, go directly to "Meta-Data and Course-Development".

How can this be achieved technically? Even while the course has semantically several independent entry points, formally it has a unique entry point with the single purpose of asking the user what s/he expects from the course and what s/he knows already. This entry point offers the user the front level modules, in case of Fig. 2 "Introduction", "Meta-Data", and "Updates of Web-Material". It might also ask some further questions in order to see whether the user is already conversant about other topics dealt with in this course.

Thus an initial dialog might be: "*This course offers you to learn about A, B, and C… . If you know already α you might also go directly to A1 or A2, if you are familiar with β, you might as well study B1, B2 or B3. However, if you are only moderately aware of η, we recommend that you look at E before going to E1 or E2. …*". It is up to the designer of the portal-page to decide whether these questions are raised as boldly as indicated, or whether a neat graphical interface or an elaborate system of an entry examination leads to the information needed. In any case, a set of concepts indicating positive knowledge results. This set can be considered as a conjunction of concepts known by the learner. Linguistically, these concepts are expressed by words either directly drawn from the vocabulary of terms used for the classification of the module or representing refinements of such terms.

If the initial dialog yields an answer of the form: *"I know A, B, and C. But I want to know X, Y, and Z."* the respective propositional term would be: $A \wedge B \wedge C \wedge \neg(X \vee Y \vee Z)$. Assume, the course contains 6 modules with the following specification:

M1:	*pre:* $A \wedge B$	*inc* C	*post:* $A \wedge B \wedge C$
M2:	*pre:* $A \wedge C$	*inc* E	*post:* $A \wedge C \wedge E$
M3:	*pre:* $A \wedge E$	*inc* X	*post:* $A \wedge E \wedge X$
M4:	*pre:* $B \wedge C$	*inc* Y	*post:* $B \wedge C \wedge Y$
M5:	*pre:* $X \wedge Y \wedge (D,2)$	*inc* $(D,5) \wedge Z$	*post:* $X \wedge Y \wedge (D,5) \wedge Z$
M6:	*pre:* E	*inc* D	*post:* $E \wedge D$

The user has the choice of immediately studying modules *M4*, *M1*, and *M2* with a certain prioritisation for *M4*, since this module leads directly to a leaning goal specified by the user. *M1* can be perused at any time, but it will be always offered as a low key option, since the user claims to know the concepts (i.e. *C*) contained in *M1* already. Hence, *M2* would be a viable alternative, since it teaches *E*, thus preparing the user to study *M3* thus reaching learning objective *Y*. Knowing *X* and *Y*, however, is insufficient to comprehend *Z*. Thus, before venturing into *M5*, the user has to look at *M6*, and using the concepts acquired in *M2* try to grasp *D* sufficiently to study carefully *M5*, a module that does not only teach *Z* but also raise the students understanding about *D* from an introductory to an intermediate level.

One can see from this example that the precondition structure defines an implicit network that needs no global perspective. The global perspective is reduced to the aspect that the individual modules (or chunks) contribute to the overall learning objective of the course. Thus, the terms used in their pre-/post-conditions (resp. increment) have to be drawn from a relatively narrow knowledge domain. Usually it is a sub-domain of some domain referred to in the general metadata classification section. Adding an additional learning concept to the course thus does not require complex updates. It is just necessary to check, whether the pre-conditions of the new module can be met at all by either initial profile specifications or by profiles updated by knowledge increments taught by other modules. It is to be noted, that the pre-condition structure is not only local to the individual modules (learning strings) but repeats itself at the chunk level. Thus, the concept of pre- and post-conditions can also be used by course builders in finding adequate chunks to be combined to learning strings and thus eventually to presented modules of the course.

4. Conclusion

The paper presents an approach to modularise and dynamically re-link e-learning content. It rests on an extension to the metadata proposed by the LOM standard. The concepts presented are implemented on top of the content management system from HyperWave (Maurer, 1996). The power of the approach rests on a stratification of connection types as well as on a flexible notion of reusable learning modules.

Abstract: The paper addresses the problem of how to share knowledge between a small group of people engaged in learning activities. In existing systems that support collaborative learning there is some evidence that difficulties occur when we try to: (1) support the sharing of knowledge between users; (2) support the learning process across distributed groups within a given educational setting; and (3) provide distributed access to knowledge from different types of machines. The proposed work is based on the examination of how a common structure for knowledge sharing can be used in distributed environments for collaborative learning in a higher education context by providing a 3D interactive visualisation. This work proposes the development of a visualisation design to convey information of the common structure for knowledge sharing to be created and enhanced in an educational context. We defend that the use of both the visualisation design and the structure for knowledge sharing can support collaborative learning.

1 Introduction

Currently, there is some pressure to improve learning environments and use Information and Communication Technologies (ICT) in innovative educational contexts [Goodyear, 1999]. The ready availability of networks and computers allows for the development of computer-networked systems that support learning activities in classrooms or distributed situations.

However, current systems for collaborative learning [Britain and Liber, 1999] do not support the same knowledge sharing environment that face-to-face situations enjoy. In particular, there are difficulties to representing context and abstracting information about the knowledge theme being discussed. This is a problem that needs to be addressed in order to facilitate support for Computer Supported Collaborative Learning – CSCL. In particular, knowledge sharing becomes even a great problem in situations where more traditional teaching, based on the presence of the teacher, is expanded to allow for both local and distance education settings [Wan and Johnson, 1994].

Additionally, some authors argue that efforts to improve learning and education must emphasise not only content but also context. In fact, already [Lewin and Grabbe, 1945] defend both that learners play an active role in discovering knowledge for themselves and the strong influence that the social environment of the learner in promoting changes. Also [Vygotsky, 1978] defends that knowledge results, not from a transmission process, but from the internalisation of social interactions.

New technologies that use 3D visualisation facilities and interactivity within virtual worlds seem to assist in minimising the difficulties by allowing abstract information, in the form of structured knowledge for representing contexts and meanings, to be visually mapped and explored using direct manipulation techniques. Such a representation can complement existing tools to allow context sharing of a given knowledge theme – a view of organising information about a particular knowledge theme.

2 Collaborative learning and the use of visualisation facilities

Collaborative learning is defined as groups working together for a common learning propose [Resta, 1995]. To collaborate effectively in work group, each individual purpose must share a common grounding of concepts and be able to specify them in a form that allows individual reflection within the group. Each user in the group must possess a common mental map representation for reference, to understand the meanings and relations underlying a particular situation, topic, or subject knowledge referred as view. The common use of a visual representation of such a mental map allows for collaborative construction and enhancement, providing the opportunity to augment both individual and collaborative learning. An example of a similar system is CSILE (computer-supported intentional learning environments), which is a collective networked database of students' thoughts in text and graphic form. Data is labelled and organised in such a way that it can be accessed allowing a student to analyse a given view and to access related information in another domain [Scardamalia and Bereiter, 1994]

Information to support the meanings and relations of a mental map can be seen as a common information set of which each user must be aware. As this information comprises abstract concepts and their relations we propose the need to develop a structure for supporting knowledge sharing for the view to be shared. Few systems explicitly support such abstract information or consider it an important issue for supporting collaborative learning [Beck-Wilson et al., 1999].

The following ideas are proposed to support both user and collaborative learning:

- a structure for representing the knowledge theme being shared;
- a visualisation design to convey information about the structure being shared;
- an environment to allow the use of the structure and visualisation design to discuss and collaboratively enhance the knowledge being shared.

The work attempts to propose a visualisation design addressing the problems of:

- cognitive overhead: by allowing a abstract high level for information representation [Norman, 1991] and thus providing the means to integrate data using Information Visualisation techniques [Card et al. 1999];
- information overload: by allowing each individual user to take advantage of a structure for knowledge sharing and thus providing a context for reasoning about a particular knowledge theme [Huhns and Singh, 1997].

Additionally, the work is also extended to propose:

- support for data source integration: by taking advantage of a visualisation to merge information about a data source with the common structure for knowledge sharing and a textual search engine for Information Retrieval.

These problems are addressed by using a 3D interactive visualisation based on a structure for knowledge sharing that describes the requisite information. The structure is used to organise abstract information that must be shared for collaborative learning. The proposed solution uses visualisation as means of creating a projected representation for the structure been shared among different users. This work extends previous research on Information and Communication Technologies in education, in particular using Internet facilities for supporting virtual environments for higher education [Gouveia, 1999].

3 Approach of the work

The study of existing practices in collaborative learning and education environments serves as an initial starting point to get insight into ways of using abstract information and how it can be of value for and between students. The study of literature about face-to-face collaborative learning situations and knowledge construction provide important insights to inform about the characteristics that a virtual world system must have, to support similar functionality.

Based on the existing empirical data and from technical solutions developed on existent systems, a number of design solutions where considered. One of those solutions is the use of a structure as the main support for sharing knowledge about a particular theme view ? context. Huhns and Singh propose that users can contribute to enhance an existent domain knowledge model [Huhns and Singh, 1997]. Additionally, Huhns and Stephens efend the idea of using a set of symbols to represent a knowledge domain to be used by each individual [Huhns and Stephens, 1999].

The use of a set of symbols in the visualisation design provides a visual mental map representation that can help to keep cognitive overhead and information overload problems minimised. [Tufte, 1990].

As one of the main characteristics of the structure that must be represented is its relationship network, the visualisation design must provide some clues to organise and orient users. The exploration of a three-dimensional space for human interaction seems a natural option to do this: Cyberspace is claimed to provide a three-dimensional field of action and interaction with recorded and live data, with machines, sensors, and with other people [Benedikt, 1991]. According to Wexelblat, a well-structured view can make things obvious to the viewer and empower interaction. The view structure can convey an underlying mental model and can indicate possibilities for interaction in what Wexelblat proposes as semantic spaces [Wexelblat, 1991].

The strategy followed for the visualisation design is to take advantage of collaboration between users to enhance domain knowledge that can be visualised and manipulated by each user for their own information needs and to allow different data sources to be integrated with the structure for knowledge sharing. This will lead to the combination of data source information and knowledge in a way that there is an independent layer between the knowledge been shared and a given data source. Thus provides the user with additional support to both analysing the data source and help in information retrieval activities.

This high level approach allows for a different kind of integration with existing data sources. It allows, in opposite to alternative low level – data – approaches no need to alter existent data sources and apply precise rules for previous identification – classification – of relevant information.

In order to test both the use of the structure for knowledge sharing and the visualisation design, a prototype has been developed to allow a group of students to use the visualisation design for sharing knowledge [Gouveia and Gouveia, 2002]. The prototype intends to test both the functionality and effectiveness of the use of the structure for knowledge sharing and a visualisation design to support user learning. The learning results from a group of activities such as collaboratively sharing, discussing and enhancing a structure for knowledge sharing.

4 Final remarks

The work defends the need to consider information about tacit knowledge as one of the requirements that must be presented in using Computer Support Collaborative Learning. Other authors defend a similar approach [Lewis, 1999; Mercer, 1995]. One main contribution of the work is the proposal of a structure for knowledge sharing to describe a knowledge theme view. This structure presents a base structure that can be extended to include and reference more information and thus provide richer semantics by adding new elements.

We claim that an appropriate approach to use the proposed structure for knowledge sharing is to provide a visual interface as a 3D interactive visualisation. A direct advantage of this approach is the possibility to represent structure relationships and integrate both knowledge and data source information.

The general outcomes of this research are:

- use of a structure to represent a knowledge theme view: conveying information to be enhanced by collaboration. The structure allows the knowledge specification, knowledge sharing and supports the visualisation generation.
- a 3D interactive visualisation to convey structure information: allowing the visual sharing and individual exploration of the structure for knowledge sharing.
- proposing a generic support to knowledge for collaborative learning: resulting in the joint use of the structure for knowledge sharing and a 3D interactive visualisation to support collaborative learning.
- provide the means for integration knowledge and a data source in the same interface: by giving a visual representation for the knowledge. The integration is made possible by using Information Visualisation techniques [Card et al., 1999].

The novel aspect is the proposal of the use of knowledge to render a 3D interactive visualisation design and an integrated Information Visualisation to combine data source information with the visualisation of the structured for knowledge sharing. Together these facilities provide an environment for collaborative learning support.

The system can be integrated with a data source, providing a tool for sharing and manipulating the visualised structured information as a knowledge map. This means that the system assists users in information retrieval actions within a specific knowledge theme view. The system provides the support for more informed browse and search tactics to be undertaken by the user. It also provides support for sharing, discussing, and exploring the structure for knowledge sharing, providing an environment for collaborative learning.

Abstract:

How an online survey was designed to market an eLearning site for Cisco Systems Technical Assistance Center (TAC) customers. Provides insights of how the approximately 7000 responses to an online survey provided customer eLearning metrics and suggestions for future eLearning content.

Statement of the problem:

A large group of Cisco customers use the TAC area of the company's website to find answers to networking solutions, learn about networking technologies, and interact with the TAC support staff to troubleshoot networking cases online. The TAC eLearning Solutions team that services Cisco's internal TAC engineers assumed the role of designing and developing eLearning materials especially for TAC customers. They designed the site to address the shortage of technical eLearning modules specifically on the TAC website. Considering the wide scope of the TAC's technical support oriented website, the TAC eLearning solutions team was challenged with: (a) offering usable and interactive technical eLearning modules; (b) selecting networking content that is suited to an online delivery format; and (c) identifying future learning needs. The team members approached these challenges by sampling other eLearning sites, analyzing the online TAC customers' training interests and finally creating a pilot eLearning site. This paper provides details on how the TAC eLearning Solutions designed, deployed and mined data from an online survey to gather user feedback related to the above issues.

Description of the activity

The online Technical Assistance Center of Cisco Systems, Inc provides a comprehensive web-based knowledge base for customers to find, learn about, and resolve networking related issues via documentation and top networking issues posted on the TAC website. A majority of the information available on the TAC WEB site is in the form of text -based notes or white papers. The eLearning Solutions site was designed to offer a variety of technical resources to help customers interact with, learn about, and resolve common technical issues. Content from thirteen different categories of networking technologies and solution are offered on this site to serve as a comprehensive learning resource for customers. The site includes short (30 minutes or less) training modules in the form of E-courses, e-labs, Netbits, and Audio-on-demands. An e-course provides in-depth network concepts, troubleshooting complex problems and network design. A Netbit is a short animated clip of a select technology or technical problem). Audio-on-demand with Flash animations offer audio and PowerPoint Slides to present the content.

After publishing the first release of the eLearning site, the TAC eLearning solutions team was challenged with attracting the TAC customers to visit and use their online eLearning resources. To address this challenge, the team advertised an online survey via an email to a list of approximately 488820, subscribed to a monthly email newsletter. As an incentive for completing the survey all the survey respondents were informed that they would be entered in a drawing to win a Palm Pilot. This strategy worked very well and the team received 5835 responses from those who visited the site. The online survey was designed to gather information related to four issues (a) identify hot topics, (b) capture user-learning preferences, (c) usefulness for customers, (d) track the technical-access to materials (e.g. browser, bandwidth) and (d) gather needs assessment for future releases. The survey instrument included a total of 10 questions. Considering the online format of the survey, the survey was designed with multiple choice (check boxes and drop down menus), rating scales, and text boxes to capture the responses. At the end of the month a web administrator provided the TAC eLearning Solutions team with an excel spreadsheet containing responses from all 5835 surveys.

Findings:

The eLearning team mined all the responses to determine the most commonly requested technology issues that survey respondents wanted to access on the eLearning site. Results revealed 13 topic areas for as

BEST COPY AVAILABLE

requested by a majority of the users. In response to the survey question "What would you like to see added or changed (on the eLearning site)?" the most frequently mentioned ones were related to requests for more comprehensive content, categorization of eLearning content by level of difficulty, and have content formatted as case studies. Several respondents also requested that the site offer a better indices and description for easier search results, site navigation, and auto-notifying users when new content is posted on the site that is related to their interests. Some of the responses also included suggestions for refining the audio quality of the video-on-demand modules and allowing visitors to download content hence offering them the convenience to view content on their own PC versus on the web.

Discussion:

The primary survey results were gathered, analyzed, and synthesized to contribute to the needs assessment phase of the next release of the TAC eLearning solutions area. ELearning content authors are currently working on 4 of the 13 most requested content areas as identified by survey respondents. The comments also helped the web developers to identify their users' profiles including their learning preferences, technical requirements, and eLearning expectations. New content posted on the site is advertised to audiences who requested technology specific newsletters. Hence the survey results helped course developers, technical writers, web designers and instructional designers to incorporate survey comments pertaining to their role in the site's ongoing development efforts. In parallel with this effort the TAC eLearning solutions team is now focusing on creating more comprehensive eLearning materials organized by level of difficulty for each technology topic area. The suggestions from the survey comments are being incorporated in the development of another version of this site containing more formal technical training curriculum organized by networking professional roles.

“And we’ll have fun, fun, fun.........!” Online Games-Based Learning

A Proposal by Bob Boufford and Bonita Bray

Introduction

Television and computer games are creating new generations of learners who "just want to have fun." Online educators can capitalize on this by implementing digital game-based learning activities using tools in course management systems that lend themselves to learning while having fun online. In this session, participants will identify key elements of games, discuss similarities to learning and explore game-based activities that encourage active learning and fun through online communication and collaboration.

Body

Both personal experience and a growing body of literature attest to the changing characteristics of our students. Raised on television shows like Sesame Street, video games and computer technology, they are used to having fun and expect to do so in most of their activities. Increasingly, they do not have the patience to sit in a classroom or read through online content modules. Even communicating with their peers in virtual classrooms can be boring.

While the new computer technology has created this problem, it also offers a potential solution, since many online course management tools allow instructors to include digital games-based learning within a secure structured online course environment. These tools allow the instructor to quickly put up course content with only minimal knowledge of web site development. However, this structured environment does put restrictions on certain activities. While using a web browser provides low hardware/software requirements for students, it does restrict the use of certain types of computer technology that is available on standalone computer systems or games consoles.

Within this course environment, digital games can range from trivia games, through role-playing and simulation, to puzzles and strategy games. In addition, while the course management system may not be adaptable to actual games, the communications features built into most of these systems allows students to collaborate while using various off-the-shelf games such as “sims” (short for "simulators") and strategy games. All of these can provide fun while teaching essential course material.

We will also explore a number of possible learning games possible in an online course such as email games, scavenger hunts, and trivia games. In addition, “off the shelf” Jeopardy-type games, card games with customized course-based questions and crossword puzzles using course materials are other types or games that can be incorporated using a mix of HTML, JavaScript, Java and Flash technologies.

We will identify what Parensky identifies as the six key structural elements of games:

- rules
- goals and objectives
- outcomes and feedback
- conflict, competition, challenge and opposition
- interaction and
- representation

While games and learning may seem poles apart in both their structure and goals, we argue that these elements are very similar to the structural elements of learning. With this information, audience members will be able to consider how games-based learning could be used in their online courses.

As an applied "example", we will share an approach we have used successfully a number of times that supports many of the seven principles of good teaching practices as established by Chickering and Ehrmann and also encourages students to engage in higher level thinking identified in Bloom's Taxonomy. In our game, "students" played the roles of secret agents in a scenario based on the original Mission Impossible television series. This simulation encouraged participants to explore the inherent characteristics of the communications tools while they experienced intense online communication and collaboration.

Virtual-Virtual-Barter For Sustaining And Developing Geographically Scattered Communities; The Example Of "Resource Communautaire Troc-Virtuel".

Gary Boyd Concordia University, Quebec Canada <boydg@vax2.concordia.ca>

Louise Sauve' Tele-Universite', Quebec, Canada <**Error! Reference source not found.**

Abstract: Virtual virtual-barter is a Web-based strategy for `free-give-and-take' or barter of resources. The SAVIE (Societe' pour l'Apprentissage a Vie) Reseau Communautaire troc-virtuel (RCTV) project makes use of a single website and special software to efficiently distribute member organisation' staff requests for materiel & assistance and their offers of assistance to others in the community. Activity tokens (bons d' echange) are generated with each action: offer, request, match, or trade, to keep a global accounting of relative participation by the various organisations and sub-groups (not by individuals) over time. The activity tokens do not correspond to person-time or monetary value of materiel. This system has been in use in Quebec for about two years, and across all of Canada for a year. Initial results will be discussed: Starting with RQuODE and ACREQ in Quebec, the barter system now includes forty organisations across Canada, The Website works well, usability needs improvements.

Introduction: -The Context and Our Main Educative Concerns

.......Our main concern is to find out how best to use Internet based technology to strengthen local cultural communities and the resource-sharing links among them, in this case especially to strengthen the francophone life-long learning community in Canada, and thereby perhaps also Canadian and World society. New communications and exchange technology may help with the very serious challenges we face. Many commercial technical and political forces are weakening our communities and marginalising large portions of the population. Seemingly unemployable young and old persons are widely disadvantaged in these times (Schragge & Fontan 200). The particular venture that we have undertaken to research in practise is one using Web technics to help (re'cherche d' emploi) organisations which help people train for and find good work commensurate with their abilities. These organisations seek to connect clients with eco-socially good lasting employment. Strengthening the core employability linking agencies in Canadian society is becoming very important and urgent. We believe that well deployed tele-technology can help the organizations which actually do help such alienated and disadvantaged persons be more effective. Since most of the organizations which help the unemployed are now seriously underfunded by government, and are but weakly sustained by charity, some new minimal-cost resource-sharing solutions such as LETS barter (linton 2002) or free give-and-take of complementary temporarily surplus capabilities seemed to be an hopeful strategic option to pursue and research in order to strengthen them. The strengthening is in three respects: first directly through shared resources, second indirectly through enhanced acquaintanceship, and thirdly through the extra evidence which a Web based exchange system can provide (via transaction audits etc.) to governments and other funders good evidence that actually so many people are working effectively together so often, in organisation X for the public good. These hard data from the auditing capabilities of Web-based exchange support systems legitimate augmented government and foundation funding. Some tentative conclusions about the practicability of this strategy based on the results to date, and some further research questions which have emerged from it are presented below.

The Strategy: A Website Facilitating Multi-lateral Resource Sharing

To be optimal for strengthening scattered communities exchange support tele-technics should be: *accessible, easy to learn, easy to use, socially convivial, valuable and reliable*. To strengthen large Canada-wide(or wider) communities, the tele-technics system should also be *scaleable* to accommodate very large numbers of transactions among large numbers of people without either undue time burdens, or detrimental side effects.

Website based systems which participants check into as needed, offer obvious advantages(Boyd 1997). The useful configurations range from very simple bulletin board swap sites(e.g. <http://www.u-swap.com/>) up to complex AI-agent brokerage systems such as I-help (Greer et al. 2001). For our purposes we clearly needed more than a listserv or a simple bulletin-board website but an AI system was beyond our capabilities. So we developed an interactive website with many facilitation tools..

Procedure

A number of surveys and focus groups were conduct to rough out the needs and the system design then Two years of developmental work was done with Quebec organisations and the prototype Website. The system design and operation protocols arrived at are given in table 1.

Final Protocols	
Context	In a difficult economic context several community employability service organisations regrouped themselves to form the virtual-virtual barter network RCTV. This network permits them to help one-another to minimise their out of pocket costs through sharing and exchanging goods services and information. Moreover this network helps draw together organisations with common purposes and complementary strengths that are geographically dispersed very widely across Canada. Free exchange, without any notion of commercialisation centred on principles of mutual aid provides an enhanced source of optimism and motivation for struggling service providers.
Variable « objects »	Any sort of "object" ('learning object', working documents, professional consultations , surplus equipment, workshops, etc.) is exchangeable. A certain number of classes of such objects have been defined by the organisations as of particular importance for sharing, and are specifically catalogued through the RCTV Website..
Formula of exchange	Each partner organisation submits a list of objects which it is ready to barter, and also a list of objects which it would like to obtain. The exchanges are made by mutual consent among the organisations as gifts to each other without use of money or scrip.
Type of barter	Multilateral, which is to say it is effected by interaction between two or three or more organisations to meet each other's current needs.
Value of the objects and exchanges	NO monetary value is attributed to the objects exchanged, nor to the tokens of exchange (bons d'entraide). (This is to avoid ill-feelings about possible unfairness, as well as to avoid attracting taxes.)
Type of currency	The organisations offer and acquire objects freely at their convenience. However to keep some trck of relative contribution and benefits a token if exchange is awarded to the provider of any object by the beneficiary. In cases where the exchange is not possible on a bilateral basis, if one of the two lacks anything of interest to the other the exchange can be multi-lateral involving other organisations. The tokens of exchange facilitate this. Since a token is remitted to the organisation which found nothing it wanted at the time it can use the token later when it does find something helpful offered by some other member organisation..
Intellectual Property Rights	IP rights remain with the authoring organisation (or its members). Before any object can be modified , or further traded permission must be obtained from the source.
Protocol for recording transactions	The network of exchanges is supported by a secure transaction system which records the sequence of every transaction for accountability. The private workspace of each organisation involved is automatically updated at the instant of any transaction.
Confidentiality of all exchanges	Total. The network is accessible only to members with passwords which give access to general offers and requests, and privileged access to the transactions of the particular organisation(s) where the person works. Each user who has

BEST COPY AVAILABLE

Final Protocols	
	been mandated to conduct exchanges by their organisation receives a unique password. All transactions are recorded confidentially
Model of association	The RCTV is a co-operative governed by a board composed of representatives of all member organisations and of SAVIE.
Membership	During the prototype development phase there was no charge for organisations to join the network. But they and their participating staff have to agree to abide by the RCTV charter of rules which specifies the modes of exchange, the responsibilities and rights of each partner member (essentially as set forward in this table).
Organisational mechanisms	Each organisation which joins the network must provide a list of 'objects' which it is ready to provide to others, and should place requests for needs it thinks the network might help it with. For each object offered the contributing organisation receives a token of contribution. When an organisation desires an object offered by another organisation it asks the other to provide the object in return for one of these tokens. of contribution. The request is automatically forwarded. The organisation which receives the request can accept, or refuse, or discuss the request by means of a private chat conference space. When the operation finishes the information is recorded in the private archives of the two organisations involved. If an offered object is withdrawn, then the ex-donor organisation loses the token of contribution it had received for offering the object
Hosting and maintenance services	SAVIE is the hosting organisation RCTV. It provides a team of secretarial and technical staff to give user help-line support and to maintain and upgrade the system. It also conducts formative evaluations of the operations and arranges face to face conferences from time to time to obtain guidance from the member organisations. (SAVIE also conducts research on the whole venture.)
Information technology capabilities provided	The RCTV Website system gives access to a range of functionalities and tools, to support exchange of resources and community building, of which the most important are: ❖ a show-window for presenting the profiles of each member organisation (mission, objectives, specialisation, clientele, etc.). A link to the member organisations own Website (if any) is provided. ❖ a searchable show window for the 'objects' offered as contributions. and a display of requests, and tools for matching requests to offers. ❖ Private exchange-status display space for each organisation. ❖ Private conferencing and chat spaces for negotiating details of bilateral exchanges. ❖ Conference for general discussion of common interests among staff of all members organisations. ❖ Conference for dealing with technical breakdowns and other operational problems

Table 1. PROTOCOLS of the "troc-virtuel" system .

Current Status of the Venture

The new Francophone pan-Canadian community virtual-barter network (RCTV) has been brought into existence and continues to function. A repertory of resources available for sharing among the various organisations has been compiled. Staff members of forty-two organisations have participated in the network's development. Face to Face workshops and focus groups have been held in Montreal Quebec City and Vancouver to introduce people to the goals and techniques involved and to obtain their feedback on usability and usefulness aspects of the network. To date, four graduate students have studied and worked on the project. Two undergraduate computer-science students have done internships with the project.

As it has developed the SAVIE/ RCTV Website software system, offers more than all the essential support functions, and is also actually accessible and reliable enough to support valuable exchanges among the organizations across Canada.. However, to accommodate some of the minimally computer-literate and very busy users in the field, improvements in the ease of learning and in the ease of use were found to be helpful. Starting with RQuODE (Regroupement Que'be'cois des organismes pour le de'veloppement de l' employabilite') and ACREQ (Association des clubs de re'cheche du Que'bec) in Quebec, the RCTV system now involves about forty francophone organisations all across Canada, from SYNERGIK in New Brunswick to CETIC in British Columbia.. Theoretically our Website software system should scale well to even much larger numbers of participants and of transactions, but this awaits empirical verification. What we have learned so far, is that the general approach is welcomed by the (francophone recherche d' emploi) community organizations. That the organisations do have a large repertoire of complementary materiel, seminars and professional capabilities, much of which they are willing to share from time to time - if duly credited for their contributions.

The virtual-virtual-barter strategy for community viability presented in this paper is engineered to be self bootstrapping to an important extent once it really gets going. This is possible and likely because of the solid politically relevant evidence it can provide about the numbers of people and the proportions of their time which are actively involved. Such evidence can be used to obtain funding and other kinds of support in on-going positive feedback loops. To fully understand the venture the history of these characteristics of the leading actors would have to be explored and verified. Fortunately Copious details actually are provided in the various project progress reports and final reports available on the SAVIE website<www.savie.qc.ca> upon which we have drawn this account..

Support for Mobile Learners in Distributed Space

O. Brand*, L. Petrak†, M. Zitterbart*†
†Institute of Telematics
University of Karlsruhe, Germany
*Learning Lab Lower Saxony (L3S), Hannover, Germany
E-Mail: brand@learninglab.de, petrak@learninglab.de,
zit@learninglab.de

Abstract: Today, learners on the move are typically disconnected from their learning environment and from other learning partners. With the advances in mobile communication, we envision distributed and mobile learners to be seamlessly connected to learning sessions and learning content. Connection should be supported in an ad-hoc fashion, if applicable, and during mobility (Zitterbart et al. 2001). Mobile learners are usually equipped with mobile devices, such as laptops or handheld computers (PDAs). This has to be considered for the development of collaborative applications. Furthermore, an integration of existing collaborative frameworks into interactive workspaces will be investigated. This requires the development of new learning scenarios that provide support for such integration.

Introduction

Learning may take place in very different settings, for example, interactive lectures or learners meeting in a coffee place. However, today, learners on the move are disconnected from their learning environment and from other learning partners. With the advances in mobile communication, we envision distributed and mobile learners to be seamlessly connected to learning sessions and learning content. The main goal of the project is to provide seamless support for learning teams in distributed space (*d*Space) where the number, quality and timeliness of interactions and communications among learners are increased (Zitterbart et al. 2001). To support learners on the move, the use of mobile clients (such as handheld devices, PDAs) has to be supported. To address these issues, distributed applications for synchronous teamwork that deal with the required scenarios have to be developed. These applications aim at the integration of mobile clients into CSCW/CSCL frameworks. In this context, the adaptation of existing CSCW applications for the integration of mobile clients will be investigated. Furthermore, the integration of existing CSCW/CSCL frameworks into interactive workspaces will also be investigated. The project focuses on experimental work, so the general approach is based on iterative prototyping cycles where the developed prototypes will be successively enhanced, tested and analyzed. Basic parts of the evaluation will be performed with the "interactive classroom" that uses small handheld devices (PDAs) in a lecture room to enhance interactivity among the students (Mauve et al. 2001). The prototypes and applications developed in this project will be enhanced based on the evaluation results.

A Framework for Collaborative Learning

The MACS (*M*odular *A*dvanced *C*ollaborative *S*ystem) framework consists of several components: networking, control, visual session control and application modules. The networking modules are responsible for communication services (i.e. connecting MACS to a local network) and support of both unicast and multicast transport protocols. The control component provides dynamic module loading and the management of sessions, users and applications. The visual session control performs graphical session and floor control in a virtual meeting room supporting group awareness as well as social protocols. Applications are modules loaded on demand at runtime. Currently, a basic set of applications like a whiteboard, a feedback tool and audio & video is integrated.

BEST COPY AVAILABLE

The GUI of MACS is based on a simple, two-dimensional graphical surface on which session and floor control is performed. The participants of the session are displayed as thumbnails, their multimedia equipment (camera, microphone, speaker) is represented by small icons placed above (cf., Figure 1). A speaker, for example, means that the participant is accordingly capable of listening to an audio stream. Various conferencing scenarios - discussion groups, lectures and seminars - are currently supported, which differ in the kind of visualization, the maximum number of participants as well as in the supported floor control policies.

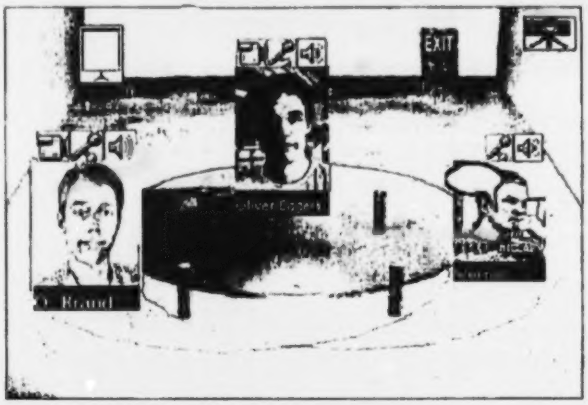

Figure1: Meeting scenario in MACS

In the meeting scenario, session control can be performed within this virtual meeting room. For example, to expel a participant from the session, the session chair just drags the thumbnail of the corresponding participant and moves it to the exit door. Floor requests for the audio resource are visualized as a *speech bubble* within the participant's thumbnail. Several floor control policies are available which contain both implicit and explicit policies.

In the lecture scenario, a virtual classroom replaces the virtual meeting room, and the participants are not displayed via thumbnails but in a symbolic way using group symbols of different sizes and colors. This addresses the scalability issue and permits lectures with a higher number of participants. The size of the group symbol varies according to the number of learners currently listening to the lecture – important information for the teacher. For easier recognition, the teacher is always visualized as a thumbnail. An encompassing overview of the MACS system and details about the supported conferencing scenarios can be found in Brand et al. 2000.

The Challenge of Integration of Mobile Learners

Currently available tools for collaborative work (CSCW/CSCL) lack support for tele-teaching scenarios with mobile clients. Two main goals are followed within this project:

- The investigation of the integration of mobile clients into existing CSCW/CSCL frameworks. In this context, tailoring the CSCW tool MACS for the integration of mobile clients will be investigated. This requires a complete redesign of the graphical user interface of MACS. PDAs offer less screen size and performance power than PCs or laptops, so this has to be considered for an adequate screen design of a CSCW framework to make it usable even on handheld devices.

- Increasing the interactivity with handheld devices. This is evaluated by the interactive classroom submodule of the project (Mauve et al. 2001). The students in a lecture are equipped with handheld devices (such as PDAs). These devices can be used in various ways: for spontaneous call-ins (to submit a question to the teacher), to get feedback from the students regarding some aspects like content, technical quality, etc.

BEST COPY AVAILABLE

Different Learning Scenarios

As mentioned above, the learning process can take place in different settings, i.e. in a lecture room, in a coffee place or at home. For these different settings, there are various learning scenarios that have to be supported by the network infrastructure as well as by the collaborative applications.
There is a variety of possible learning scenarios existing:

- All participants meet in *one* room, so all members are physically present. This can be used for teaching scenarios as well as for interactive meetings, such as brainstorming.
- All participants are physically distributed, potentially mobile, and are communicating with collaborative applications. This can be used to let physically distributed people interact and share the same workspace and/or applications.
- A mixture of the above scenarios: some participants meet in one room physically, and some other participants, physically distributed, are connecting to this meeting via collaborative applications.

Today, learners are often equipped with mobile devices, such as laptops. The use of smaller handheld devices, such as PDAs, will increase in the near future. These devices are easier to handle than laptops, but are less powerful in performance and offer only limited screen space for applications. To deal with these restrictions, new scenarios have to be developed to enable learners on the move using a small PDA still to connect to their learning environment.

The iRoom

The Stanford Interactive Workspaces project, also known as the "iRoom" (Stanford 2000), is an example for a learning scenario that deals with mobile clients. Its main goal is to explore new possibilities for people to work together in technology-rich spaces with computing and interaction devices. The desired scenario corresponds to the first type listed above: *all* members of a working team meet together in *one* physical room, the iRoom. This room functions as a dedicated meeting space equipped with enhanced technological environment such as large displays, wireless I/O devices and the opportunity for integrating mobile devices such as handheld PCs. The team members can share all technical resources in the iRoom. This enhances the communication between the team members and therefore improves the global working process. Here, the focus lies on task-oriented work, such as brainstorming meetings or design reviews.

Currently, there are a couple of features for the iRoom available enhancing communication among the members. *Multibrowse* represents one of them. It allows the "beaming" of a web site from the Internet Explorer to one of the integrated displays in the iRoom. This can be used to share a web site from a participant's laptop with all other present members in the iRoom. For the realization of the multibrowse features and to provide better communication support between members, the *EventHeap* (Johanson et al. 2001) is used. The EventHeap is a small, JAVA based application with client/server architecture. The server controls the applications being used in the iRoom, e.g. an Internet Explorer being visualized on a large display. The client runs on the participant's mobile devices (i.e. laptops or PDAs) and receives events from the local applications, e.g. a web browser. These events are sent wireless to the EventHeap server which analyzes the events and performs the corresponding actions. This feature can be used for a variety of applications, e.g. "beaming" of web pages from a participant's laptop or PDA onto the large displays in the iRoom.

Integration of MACS and iRoom

One possible approach for an integration of the CSCW framework MACS into the iRoom deals with the mixed scenario explained above. Some members of a distributed team are physically present in the iRoom and can use the existing infrastructure. They are able to see and talk to each other. Some members of the team are physically distributed and are connected via the MACS framework to the session in the iRoom. The entire scenario consists of a "mixture" of physically present and remote participants. In this scenario, some problems regarding session and floor control may arise. First, there is the possibility of not considering the presence of remote participants in a discussion or brainstorming. The awareness of the physically present members in the meeting may lead to ignore the remote participants, e.g. for determining the next speaker. Secondly, social protocols, which normally help to control an ongoing conference, might not work as expected. The mimics and gestures of the physically present participants are easy to recognize, but those of the remote participants may be much more difficult to identify, perhaps owing to insufficient audio/video connection or a temporary network loss. A solution for these problems might be the use of video screens. Such a video screen being located next to the physically present members represents each remote participant. In this way, a mixture of physically present members and remote members in the meeting room is created, where the physical members are aware of the presence of remote members. To overcome the problem of the use of social protocols, still images of the remote participants instead of live videos could be used. These images can be expressed with some actions regarding floor and session control. A rising hand may be indicated by the visualization of a speech bubble within the image, and the temporary absence from the meeting may be indicated by the text "back soon" within the still image of the member, just like in the MACS framework explained above. In this way, the feeling of group awareness regarding *all* participants of the meeting – not only for those who are physically present - can be mediated.

The EventHeap structure can also be integrated in the MACS framework. The EventHeap integrated in MACS may interact with the EventHeap structure of the iRoom: The whiteboard application integrated in MACS, for example, may send events to the whiteboard application running in the iRoom, where the events can be used to synchronize both whiteboards and to ensure a common view for both, local and remote participants.

brazile@cs.unt.edu

Abstract: This paper is a description of the software architecture of the International Collaborative Environment (ICE), a system implemented as a collection of components written in Java. The system allows groups to collaborate, both synchronously and asynchronously, to perform tasks over the Internet. The ICE components, all of which are shared by users in the same group, are chat, whiteboard, editor, file sharing, help, web browser and desktop sharing. In addition to the components provided by ICE, a user of ICE may develop and install additional components of their own design. These user-written components may take advantage of the collaborative features of the ICE system. This feature makes the ICE system user-extendable and able to respond quickly to new and different requirements of users.

Introduction

The functionality of ICE has been described elsewhere (brazile et al 2002). Here is a brief review. ICE allows a person to join a pre-defined group and use the components of the system in a shared synchronous mode although some features such as file-sharing and chat history support asynchronous use of the system. Members of a group may chat with each other, draw using the whiteboard so that all members of the group see the same drawing, and use the shared editor on plain text files. They may use the web browser to surf the Internet and lead the other members of their group to the same site. They may share files with other members of the group using the file-sharing component. They may allow other members of the group to see their desktop and watch while various programs are executed. A user may also allow another member of the group to take control of their desktop and execute programs on the user's workstation.

ICE is an evolution of a system developed by the authors called the Virtual Collaborative University (VCU) (swigger et al 1997). VCU had many of the same collaborative tools but was implemented using C++. A decision was made at the start of this project to implement everything using Java. By using Java exclusively, the system is capable of running on any platform that has a Java Virtual Machine. The ICE system has been tested on all Microsoft Windows operating systems, and several versions of Unix including Linux, Freebsd and Solaris.

Architecture of the system

Software for ICE is divided into four sections: Server, Client, Administration and Core. The server portion is small and handles only the initial startup of each client and the shutdown of each client. The client is larger and contains the launcher and the main program for the client process. It also contains the component modules of the system. The administration contains programs used in the administration of the system, such as transferring log files into the system database. The core contains programs that are used by more than one of the other three sections.

Server

The server listens on port 3000 for clients who want to connect to ICE. The server is task oriented so after accepting the connection, it waits to receive a command from the client. Currently it can perform four tasks:

1. VERIFY: after a user enters their username and password, the client sends a verify message to check if it was valid. If valid the server will send back information for the user (name, email, etc) and a list of the groups that the user may log into. If the username and password are not valid the server sends an error message and the client asks the user to try again.

2. CONNECT: The user may select either the default group, or select an alternate group from the list of groups available to this user. After the user chooses a group, the client sends a connect message telling the server to enter it in the Active User table. The server will send back the current time for synchronization, the IP address of the user and a list of users who are currently connected. Once the client has the user list, which includes IP addresses, it communicates directly with other clients. It communicates with the server only for keep-alive messages (see 4).

3. DISCONNECT: when the user disconnects, this command tells the server to remove the user from the Active User table.

4. CHECKIN: the client sends a keep-alive message at some interval (currently 10 minutes) to the server. If the server does not receive the message it will remove that client and tell group members. This allows the system to automatically handle users that killed the software, did not shutdown properly, lost their Internet connection, etc., though it will take some time before they are removed.

The server contains an FTP server that accepts log files from the client. Log files are sent by the client after twenty log messages have been generated and at the end of a session. The number of log messages before sending the log file, currently defaulting to twenty, may be changed in the client's ICE configuration file. If the system is interrupted before the last log file is sent, the client will send it the next time ICE is started.

Client

The client is divided into three sections; the launcher, the ICE main module and the ICE plugins or components. The launcher starts first and contacts the ICE HTTP server to download a file named iceversion.txt. The current version of the ICE client is stored in a file in the ICE home directory on the client machine. The launcher compares the version numbers and if the downloaded file indicates a newer version is available, then the launcher downloads and installs the newer modules. Only modules that are newer are downloaded. Once the system has been updated, the ICE main module is entered.

The ICE main module is designed to be a flexible container for plugins. This consists of providing user management, networking (between other clients and between the server), and the ability to configure the placement of plugins within the system.

The user management capabilities include keeping track of the active users and the user of this system. When a user connects to a group it notifies everyone who is currently active in that group that the user joined. Similarly, when disconnecting a disconnect message is sent to group members. If the connect attempts fail the user will receive a notice that the system could not connect to that user. If the disconnect fails, no notice is given. However, the keep-alive system allows the remaining clients to keep track of group members. When the client checks in to the server, it will update the active user list if needed. This is how individuals not in your group are maintained. If you select a user who is not in your group to send a message to and they have disconnected, the send will fail, you will receive a notice and that user will be removed from your list. This approach allows the system to minimize the amount of traffic and overhead associated with precise maintenance of the users not in your group. As the number of people in a group is usually small compared to the total number of people on the system and communications are generally within the group, this helps keep network traffic small.

The networking part makes it easy for the plugins to communicate without having to know about all of the details. It uses non-blocking I/O so that all of the accepts and reads from the different users can be done within a single thread. As most users have a single processor this increases performance and reduces the overall memory use (java applications typically require a lot of memory). Since most communication is within the group, persistent connections are set up with group members. When the user connects to the group the connection is established. The user who created the connection is responsible for the connection in case of a failure. This means that the user who first initiated the connection will try to reconnect to the other user if there is a failure. If the reconnect fails the user will receive an error message. The other user will receive an error message as soon as the problem is noticed. For users who are not in your group the system will create a new connection each time you want to send a message. The connection is then closed. This means that it is more efficient to send to group members because you do not have to wait for the connection to be set up each time. As most users send few messages to users outside of their group this is not a problem.

The placement of the plugins is done through the two main configuration files (ice.ini, menu.xml). The ini file allows you to position the components in cardinal directions and in the center. These components are separated in a Java Splitpane so that the size of each can be adjusted by the user. The XML file for the menu allows you to configure the menus so that when a menu item is pressed the system calls a method associated with a plugin or the system (e.g. connect or disconnect). A special method (<init> which is the bytecode signature for constructors) is used to denote that the plugin should be shown in a dialog. In addition plugins can be created that hold other plugins on the interface. For example, in ICE there is a special plugin that shows other plugins in internal frames. This special plugin will show the other plugin when it receives its class name from the menu or via another plugin.

Built-in ICE components include chat, whiteboard, editor, web browser, file sharing, desktop sharing and help. Each of these components may be configured or not, for any individual client. This configuration is indicated in the ICE.ini file located in the ICE home directory. The ICE main module reads the ICE configuration file to determine which modules are configured for this specific client and where they will be positioned on the screen. This may be changed by the user. The main module then loads the configured modules and begins the logon process as describe in the server section above. The main module is responsible for logging on and off the system, sending messages to the group, getting user information, logging and error messages as well as managing the use of the various components of ICE.

Administration

This part of the system contains utility type programs that generally run separate from the ICE system. For example, there is a program that imports the local logs into the database. There is another program used for generating some of the help files in the different formats (all in one, by chapter, by section, with or without images etc.) The clean up program to remove dead users from the database is here. There are also some testing tools, for example a stress test for the FTP server to see if can handle a lot of traffic and a checking tool to see if the log files are in valid XML format. Many of the administrative functions have been moved to a web site that was created to support the ICE system (http://zeus.csci.unt.edu/).

Core

The core is part of the system used throughout the other parts. This includes the network message format (class Message), database access (class DataUtils), and XML conversion for basic types (class XMLDataUtils).

Message takes care of reading and writing data. For example, as client and server send messages back and forth to communicate, the formating of the messages is done there. A message is composed of one to any number of instructions. An instruction is made up of a type and a string for other data. The composition of the string depends on the type. For example, to use the whiteboard it might be:

Type: COMPONENT

String: Whiteboard:<shape type='rectangle'>other information needed for shape</shape>

The database is set up to hold data for three entities: users, groups, and logs. The basic types (User, Group, Log) are used to represent this data as Java objects. Basically, DataUtils converts to and from the database and those types, and XMLDataUtils converts to and from an XML format string and those types.

The remaining program in the core is Talkback. This program is used to help find problems in the software. For certain exceptions that are thrown, Talkback is used to send an email to the developers, which contains a stack trace, system properties, etc, so the problem may be analyzed.

User written components

Additional components to extend the functionality of the system may be written by the user. These components must be written in Java and must extend the class Plugin. Once written the components must be configured in the ICE.ini file and placed into the class path of the client machine. The user must implement an abstract method, getName, that returns the unique name of the component. The component inherits a set of methods that may be called to get information, such as getting User information or to use system functions, such as logging.

The user information is returned as an object and contains the user login name and other information about the current user. In an email client, for example, this information may be used to set the "from" information in the email being sent. The logging method writes an entry to the log file, which will be placed into the ICE database. These log messages may be analyzed to determine how the system is being operated by the user.

Two sample user written components have been produced to illustrate the capability of the system. The first one is an email client component that allows a user to send email to other group members from within the ICE system. The second one is a voice component that allows a user to establish a voice connection to another member of the group.

Conclusion

This paper has described the software architecture of ICE, a system written in Java that may be used by groups of people to solve task oriented problems over the Internet, where the individuals in the groups are in geographically separate locations. Readers can access the ICE system by visiting http://hera.csci.unt.edu where they can download the software. A test/demo system has been set up with five groups and a number of guest IDs. Once you have the software installed, you may logon with an ID of guestXX, where XX is 01-50. The IDs 01-09 and 50 default to group 1, 10-19 default to group 2, etc. Any of the guest IDs may sign on to any group. These IDs do not have passwords.

Knowledge Management Systems in Schools or How to Sort the Garbage Can?

Andreas Breiter
Telecommunications Research Group
University of Bremen
P.O. Box 330 440
28334 Bremen
Germany
abreiter@tzi.de

Abstract: Building knowledge management systems for schools is a difficult task. The organizational structures and processes can best be described with the garbage can model from organization theory. Ideas, concepts, solutions, decision-making come and go without defined structures. Nevertheless, a group of university students from computer science have tried to gain information from the end-users in schools about their requirements for such a system and to develop a web-based knowledge management system. The idea of student's projects in computer science as part of the degree and as an option for self-centered student learning in the special case of system development for e-learning systems will be described.

Introduction

During the last decade, many countries have started programs for the diffusion of information and communication technologies (ICTs) in schools. It is no longer disputed that digital media technologies play an important role in teaching and learning processes. The goal of computers and internet in classrooms is better teaching and student learning – usually measured by achievement in standardized tests. According to empirical studies on learning effectiveness in the past, there is no hard evidence that the use of ICT for learning is more effective than traditional ways. Some studies found an increase in student's motivation and in the development of basic skills, other studies found ambivalent results – depending on the way ICT is integrated into the curriculum. Although there is this lack of empirical evidence, politicians, industry and foundations put billions of Dollars into hard- and software and telecommunications infrastructure. This is what I call the 'learning effectiveness paradox'. It is derived from the well known 'productivity paradox' described in IS literature (e.g. Brynjolfsson 1993). According to empirical studies, it is difficult to proof that the company's productivity is increasing due to investments in IT. Following the history of IT in companies, the great expectations about higher student achievement, increase of teachers' productivity and promises about new values in teaching and learning which are connected to the diffusion of IT in classrooms should be treated with caution. Nevertheless, the increasing number of digital content confronts teachers and students with the problem of storing, selecting, qualifying and using the existing material. It is assumed that knowledge management systems will help teachers and students for co-operative learning (Koschmann 1996). But the internal co-operation and communication between staff not only in German schools is underdeveloped. This is due to the institutional framework conditions and the intra-organizational structures. The following paper describes a software development and implementation process for a knowledge management system that was organized as a student project at the University of Bremen in the faculty of computer science. It is divided in two parts: (a) the organizational problems of schools in their decision making processes and the resulting difficulties in developing a knowledge management system, and (b) the learning process of university students during the typical software development cycle.

Theoretical Background: the Garbage Can Model in Organization Theory

In organization theory five interrelated aspects determine output and outcome of organizations: social structure, technology, goals, participants, and their relation to the environment (Leavitt 1965). Referring to schools as social organizations, only few studies point out that the interdependence between schools and their environment significantly shapes the outcomes of IT integration. Framework conditions such as budget autonomy, human resource management, information and knowledge management as well as the management of change play a crucial role for a successful integration of ICT. The results of the Programme for International Student Assessment (PISA) highlight the importance of budget autonomy and school-based control over educational resources: "students tend to do better on average in countries with more autonomy, particularly in choice of courses and in budget allocation" (OECD 2001). Autonomy is a key factor for the quality of teaching and learning, and it can be assumed that this leads to a better integration of IT in the classroom. In this case, IT can be regarded as a 'trend amplifier'. For this reason, using IT for better co-operation and communication for teaching and learning seems to be helpful. But, a direct transfer of concepts for knowledge management in business to schools is difficult. Schools can be seen as 'loosely coupled systems' (Weick 1976). Teachers are highly autonomous in their decision making processes in the classroom; on the other hand, the state sets criteria for the organization and restrict the individual action space. Pupils as the largest group have only limited rights and are compelled to be part of the organization (as in prisons). The decision making processes can be described by the 'garbage can model' which was introduced by Cohen et al. (1972). Organizations of this type have unclear goals which are not set a priori but derived from action, the members do not fully understand the inter-relationship and they do not participate regularly in the decision making processes (Cohen, March, & Olsen 1972). Although adequate in some respect, this model underestimates the importance of political interest and power within organizations. Crozier and Friedberg (1977) have developed a model, in which organizations are understood as the political process of constructing and maintaining orderly patterns of interaction among a set of individual and collective actors linked by strategic interdependence. Therefore, less structured and formalized fields of action come into play (see Crozier & Friedberg 1977). Especially in schools with their hierarchical structure and individual autonomy, political power games between departments, principals and staff as well as with parents and district officials cannot be ignored. This delivers a theoretical concept about the character of the inter- and intra-organizational decision-making processes in the school system and the constraints for developing a knowledge management system. Why is this so complicated in schools? (1) Co-operation and communication are not much developed, collective action ends at the classroom door; (2) especially in German schools, there is no space for co-operation – school time is in the morning, the working place for teachers is alone at home in the afternoon; (3) the individual efforts of developing content is high, there are no incentives, i.e. it will not be shared with other teachers; (4) traditional forms of paper-based exchange of teaching material are not working – why should a digital platform? These constraints built the background for the student group to understand the complex decision-making process in schools with respect to build a knowledge management system.

Learnweb – a University Student's Project in Computer Science

At the University of Bremen, all students in computer science have to participate in a two year project that follows the system development process from requirements analysis, specification, design, test and evaluation. During the two years, the group of approximately 20 students form their own project management, quality control systems and produce a final report with all systems specifications. The professors work as moderators, giving input and help for specific topics. One day per week is reserved in the schedule. The projects range from programming virtual soccer teams, to the development of geographical information systems or the conception of protocols for an 'intelligent' house. In our field, applied computer science, we are mainly interested in projects that are connected to workplace experience and the 'real world'. The real world in our project are four schools with their teachers and pupils. The basic idea of student projects in Bremen is to support self-centered learning processes. As future employers in software companies will not only expect clever programmers but team workers with social skills, the concept of building teams of students to develop a system with requirements they have analyzed, seems to be one way of successful university education. In the case of learnweb, the students learned how to develop a web-based e-learning system (see <http://www.learnweb-bremen.de>). In parallel, we have given seminars on learning theory and paradigms and on e-learning development strategies as well as media ergonomics. Additionally, researchers and developers in the field of e-learning have been invited in order to exchange ideas. Thanks to a cooperation with a software company, the students received additional help in professional systems development. Although system development concepts such as participatory design (Schuler & Namioka 1993) or joint application development (Wood & Silver 1995) have been already introduced theoretically, most students see themselves as 'lonesome cowboys' in front of a keyboard. The project in Bremen confronts those 'hackers' with team work and gives them the chance to learn about requirements engineering.

Market Analysis

The project started with a market analysis of existing products. With the following criteria, several products were evaluated together with future users: functional requirements (necessary and preferred functions); use cases with different scenarios; usability; information infrastructure; and financial aspects. The students found products that fit many of the requirements set by the user group. But they had two major obstacles: cost and system platform. Most products with good rating were too expensive for schools, and others could not be used on Apple Macs – Bremen is the only public school district in Germany, where they are still widely used. From the market analysis, the students developed a basic functional framework which was then discussed with schools.

Requirements Analysis

Requirements analysis is the least technical phase of system development, but the most important. If not done thoroughly, the consequences are more serious than in other phases. On the other hand, too much participation of the special group of end-users (teachers) can lead to unexpected twists and requirements that can be hardly met. Nevertheless, the downstream costs of not capturing, omitting or misinterpreting user requirements may prove unsustainable later in the process. Within the requirements analysis it is necessary to define the expected services and constraints that the system must obey. All services have been clustered to describe the scope of the system and its functional features. The concepts of system development end with the requirements document were all requirements that have been accepted by the user are defined, classified, numbered and prioritized. Today, we can assume that the user will play an important role in the cyclic development process. In order to examine the work processes of teachers, the students took part in classroom activities, monitoring the use of digital media. The results were drawn in UML activity diagrams and use case models. The biggest problem of the requirements analysis are methods of requirements elicitation. There is one systematic problem (tacit knowledge of domain experts), and one practical problem: missing methodological know-how by students of computer science (interview techniques, questionnaires). Interviews are an excellent form to gather the right information. In interviews with teachers and pupils it was possible to elicit most user requirements. The students combined structured and unstructured interview techniques. Additionally, they developed a questionnaire about the functional requirements. In some schools, a group of students observed the pedagogical process from course preparation to testing. The requirement document was finally discussed with the user groups and agreed upon. In summary, the key requirement from teachers was simplicity for non-expert users. The problem for the student group was to operationalize this requirement. After longer discussions with teachers it was clear, that it meant the level of expertise that teachers have reached after participating in an introductory course on how to use digital media in the classroom. The end-users also made clear that a complex authoring tool would not be necessary because either it is too basic for the experts who use other tools or too complicated for non-expert users. The end-user also asked for a detailed help system with self-explaining hints.

Design and Prototyping

Today, prototyping is the most frequently used methods of systems development. Prototypes are constructed to visualize the software system as a demonstration. In the literature we find horizontal prototypes (complete functionality of one level of the system, e.g. the graphical user interface) and vertical prototypes (one functional part of the system is usable with a simple user interface but full functionality, e.g. the document management system, Budde 1992). It is an effective means to elicit requirements difficult to obtain in other ways. Especially, when working with teachers as non-expert PC users (but pedagogical domain experts) and pupils as expert PC-users (but non-experts in the pedagogical domain), the demonstration of use cases with a prototype was very effective. Additionally, using an evolutionary prototype helped both the students and the end-users. The students could reflect their own work processes and the end-users could directly participate in the workflow of the system development process. The requirements were directly implemented in the design of the system's architecture:

- *Personal Account (MyTeaching / MyLearning)*: Individual space for teachers and students, where they can organize their files, data, e-mails, appointments.
- *Document Management*: Upload and download of all formats. Storing and coding with metadata according to the standards set by IEEE Learning Technology Standards Committee (LTSC).
- *Communications*: E-mail, chat, electronic bulletin boards.
- *Calendar:* Personal view and school-wide view with reminders that can be sent via e-mail and short messaging system (SMS) which is very popular in Germany.

- *Resource Management:* Booking system for computer labs, laptops, beamer or other movable resources.
- *Administration:* Easy to use, decentralized administration. Import and export of data files.

Testing and Evaluation

In software engineering, much effort is used for formal testing methods. In this application-oriented project, the emphasis was on usability tests in order to specify if the user requirements were met by the systems design. The students used expert-based and user-based usability tests, following ISO standard 9241. With these methods they were able to modify the software system, focusing on the specific needs of end-users in their organizational environments. Although the complexity of schools as social organizations and the difficulties of formally specifying the user requirements were known, the period of usability tests brought new insights about the intra-organizational structure of schools. This led to additional features of the system such as a detailed help system, self-explanatory warnings and the resource booking system.

Conclusion

The process of developing a knowledge management system for schools was successful regarding the two objectives with which the project started: (1) Offering university students in computer science an application-oriented option to learn how to develop a software system in a team; and (2) creating a product that is used in the real world of schools and which helps schools to organize their internal and external communication and co-ordination processes. Within the student's group, there was a split into three peer-groups: hackers, writers / presenters, and evaluators. Although the project management tried to find a way around these strong structures, it was often necessary for the professor to intrude. The naive idea about team work for its own sake did not work. The students expected individual marks and verified unwillingly the well known phenomenon that only marks (instead of other incentives) create the necessary pressure to work. Apart from these obstacles, all three actors involved, students, schools and professors, agreed that this form of teaching and learning should be continued and extended. The organizational problems within schools still remain, the practical tests in the future will show how much the system is used and which functions are adequate.

Internationalising the Interface for e-Learning

Ian Brown
University of Wollongong
Australia
ian_brown@uow.edu.au

Abstract: This paper addresses an important and neglected issue in e-learning: user interface designers must acknowledge diversity, recognise differences to communicate effectively. Creating successful cross-cultural interfaces goes beyond tokenistic mechanics, such as, numerical formatting but instead should look more closely at local understandings or a variety of interpretations by the user. Although e-learning has had a dramatic rise in the past few years, research in the area of interface design for cross-cultural users has remained minimal. This paper explores current research on internationalising learner interface, provides evidence from two cultural settings and proposes a number of significant proposals for instructional designers and educators.

In an era where virtual worlds impact on learning and borders cease to exist, course designers must truly transcend national boundaries and cater for a new generation of learners. User interface designers must acknowledge diversity, recognise differences and communicate effectively. Creating successful cross-cultural interfaces goes beyond tokenistic mechanics, such as, numerical formatting but instead look closely at local understandings or a variety of interpretations by the user. This paper proposes a broader understanding of design issues for international users, focusing on more inclusive pedagogical issues. Consideration is given in particular to basic interaction factors and cross-cultural/internationalisation issues. Although e-learning has had a dramatic rise in the past few years, research in the area of interface design for cross-cultural users has remained minimal. As Boor and Russo, acknowledged back in 1993 'research on the topic of designing for international users is sparse'. Acknowledging there has been limited research in the area of cross-cultural translation issues, such as images, symbols and colour, very little has been written that explores the unique connection between cultural awareness, interface design and pedagogy.

As Russo and Boor (1993) claimed 'cultural awareness is an area of human computer interface which is sadly neglected'. The computer interface design areas that require further exploration include: traditional computer human interaction international issues for interface design and interactivity. The integration and connections between the three areas is what really supports successful interface design. According to Laurel (1990), an interface is a contact surface that reflects the physical properties of the interactors, the functions to be performed and the balance of power and control. The complex nature of interaction, the multi-layers that users often bring to the exercise, including cultural considerations, cannot be overlooked.

Traditional computer human interaction considerations

Interactive multimedia poses unique design problems. The experiential nature of multimedia presents users with unique interaction elements or problems to solve. Text, animation, multiple screens, hyperlinks, sound and video add complexity to the interactive environment. The computer human interaction (CHI) environment regularly researches factors that affect the success or failure in interaction with computers. According to Boling and Kirkley, (1995), interactivity is the result of design decisions and that 'quality of design' is supported by the type of interaction desired by the designer and the type of interactivity appropriate for the learners, content and context. The integration of the experience measures the success of the design.

Designers need to construct meaningful frameworks for making appropriate decisions regarding visual design and user interaction. (Boling, Bichelmeyer, Squire, Kirkley, 1997). In the early nineties designers were calling for well designed and documented standards or principles which could translate the equivalence of print based guides to digital forms. At the time graphic interface standards were being written for tool oriented software without looking at the integration of text, graphics and hypermedia links. (Lynch, 1994).

Naturally, consideration should be given to what users expect and need, providing for effective two-way communication. Basically, interface needs to be easy to understand and use. Advances in technology, especially the nature of multi-media instruction, have provided an increase focus on the visual aspects of the interaction. While standard controls, such as icons and menus have provided consistency for the user and computer developers have adopted similar interactions across platforms, there still remain idiosyncratic blocks for a variety of users, especially across cultures.

The designer's goal is to provide a positive interface that supports the user regardless of the cultural context. The user will benefit from simplicity, usability and accessibility. Efficiency for all users results from a well organised interface. Functionality should be readily apparent, void of cultural constraints. Therefore, a minimum number of actions or functions are required to achieve a particular task. Visually, the designer must adopt universal conventions. While arguing for universal conventions there are many purported 'universal actions' that may in fact, not be universal at all. Cultural aspects may need to be considered. The designer must acknowledge both the advantages and disadvantages of the complex nature of multi-media instruction, and provide security for the user. Visual design is an integral part of the design process which should communicate functions without ambiguity and support the user. Visual design skills affect all aspects of multimedia design. Basic visual design skills are a minimum requirement for all designers of interactive multimedia to support the principles purported for success. (Brown, 2000).

Internationalisation for interface design and interactivity

'Understand the users' can be a simplistic statement that demonstrates the obvious, except when the users are drawn from a variety of cultural locations and contexts. Generic and consistent interfaces may be appropriate for some instructional situations, while more authentic and culturally context driven, could be more suitable. Where appropriate, adoption of universal interfaces that draws on prior learning and builds on existing knowledge should be applied.

Badre (2001) undertook a recent study to determine whether any design elements were repeated in different cultures and genres through the World Wide Web. He named the elements that were culture and genre specific. According to Badre, these 'cultural markers' are interface design elements and features that are prevalent with a particular cultural group. Cultural markers signify cultural affiliation. These could include a national symbol, colour or spatial organization. Regardless of cultural context, designers can adopt appropriate mechanisms that ensure usability is obvious, intuitive and conducive to meaningful learning. As a designer of multi-media instruction, the basics of interaction, such as use of metaphors, manipulation, consistency, control, simplicity, support, accomplishment, satisfaction and visual design (aesthetic integrity) are worthy principles to strive for. But what other considerations are required when multi-media instruction becomes global affair? Surely, the user's conceptual model in one culture cannot be same for another. Generic or universal interface concepts cannot always be applied when diversity in cultures exists. Questionably, many who provide human computer interface principles rarely raise the issue of cross-cultural differences and the need to account for them. A major consideration for the designer is the cultural context of the user.

An example can be provided to illustrate the current lack of cultural context considerations in user-interface design. That is, a summary of principles proposed by Talin (1998) from ACM. Talin proposes 'a compilation of fundamental principles for designing user interfaces, which have been drawn from various books on interface design'. The fourteen principles proposed are the principle of user profiling, the principle of metaphor, the principle of feature exposure, the principle of coherence, the principle of state visualisation, the principle of shortcuts, the principle of focus, the principle of grammar, the principle of help, the principle of safety, the principle of context, the principle of aesthetics, the principle of user testing and the principle of humility. Conspicuous is the absence of any issue relating to culture. Perhaps a fifteenth could be added 'the principle of catering for cultural diversity'. International user interfaces issues should be considered when instruction or multi-media product is delivered in more than one country. According to Nielsen (1996), consideration of the special needs of different cultures is imperative in the design of user interfaces for international use.

Schneiderman (1992) raised the issue of cultural issues in interface design when stating 'little is known about computer users from different cultures, but designers are regularly called to make designs for other languages and cultures'. It appears that little has changed. According to Shih and Goonetilleke (1998), user interface guidelines have been developed predominantly in English speaking countries, but aspects related to culture (e.g. local metaphors, symbols, colour and flow) are not universal and have received little or no attention. They propose that the design of culturally and linguistically adapted human-computer interfaces for other cultures be adopted and specific studies are needed to test relevant characteristics of computer interface for users from diverse cultural backgrounds. While AlHunaiyyan, Hewitt, Jones, and Messer (1999), contend that culture is a discernible variable in interface acceptance and interfaces should be designed to accommodate users' cultures.

According to Marcus (2000), current user interface design is based on psychological and social models drawn from European and American research traditions, while recently, cultural psychologists, cultural anthropologists, cultural sociologists and designers have begun reconsidering the applicability of these models by identifying cultural preferences and value orientations more prevalent in Asia, Latin America, the Islamic world and Africa. Between 1978-1983, Dutch anthropologist Hofstede, conducted detailed interviews with IBM employees from fifty three countries and proposed that world cultures vary along consistent, fundamental dimensions. Hofstede identified five dimensions: power-distance; collectivism vs. individualism; femininity vs. masculinity; uncertainty avoidance; long vs. short-term orientation. Marcus and Gould (2000), examined Hofstede's dimensions and applied them to user interface and web design outlining a number of significant implications/considerations in relation to internationalisation issues. Considerations included issues such as, focus on expertise; the importance of the social role; motivation based on achievement; prominence/importance the underlying sense of morality; limits to choice, redundant cues, navigation schemes; complexity; the desire for results and achievement of goals. Marcus and Gould were able to identify World Wide Web sites where Hofstede's dimensions could be applied, suggesting that interface designers should consider the cultural differences in relation to factors such as, power and gender.

Conclusion

As educators we know that all students come to subjects with different thinking and learning styles, but now as we approach these unique technological learning situations, the diversity is much more transparent (Brown & Hedberg, 2001). We must realise the needs of students from other countries and cultures and recognise that at times the lack of shared meaning can make communication difficult for people of different cultures. As instructional designers we must recognise and provide appropriate interface for these learners. As course developers we must also consider the appropriateness and relevance of the content being presented.

Questions arise to what is appropriate for inclusion in a multi-media course instruction. What content is needed? What skills should educators develop? What course components should be categorised mandatory or elective? The problem of content selection could be (and should be) as problematic as the delivery of the course. Visual design skills affect virtually every aspect of software interface design. Students need to develop skills in areas such as, spatial relations or layout, perceptual or aesthetic principles (that is, proximity, similarity, continuity, closure etc), designing for computer screens, graphic interface design, visual design conventions (such as, typography, or colour), animation, sound. There are many principles relating to interface design that should also be developed and included in course. Importantly, as course designers of subjects that includes interface design, we must also provide cross-cultural design considerations as outlined in this paper. Students need to be aware of the role of visual communication and the impact on the learner. A successful on-line course, web page or educational multi-media package needs to bring together all the elements of successful interface. Success for all users.

A Development Framework for Re-useable Learning Resources for Different Learning Styles and Requirements

Catherine Bruen
Centre for Learning Technology
University of Dublin
Trinity College
Ireland
cbruen@tcd.ie

Abstract An existing Adaptive Hypermedia System in use in Trinity College allows for student customisation of a course. However, the author has decided to examine the considerations and aspects of learning styles that could make a considerable pedagogical impact on both the narrative selection - using Gregorc's model - and then the content selection - providing for fine grained learning - using the VARK model for learner preferences. A descriptive framework or mechanism was created against pedagogical considerations, for the metadata that would determine the three levels of adaptivity – Narrative Selection, Content Group Selection, Candidate Selection. The author set about modifying the way the information is currently modelled (the pagelets representing SQL content are created using XML) to allow for learning style specific content. The metadata was then reconciled with the current learning content. The design of the narrative model was investigated and the relevant changes were made in order to support personalized learning based on the preferred cognitive or learning styles of the students. The rules dynamically generate the navigation structure (this is the personalized process) based on the learner and content metadata, which is derived from the descriptive framework.

Introduction

One of the challenges in teaching is trying to meet the needs of a variety of students. This is particularly challenging in large classes, where the typical teaching mode is heavily dependent on lectures. In the majority of learning environments a generic course is presented to the learners and a "one-size-fits-all" philosophy is imposed with little or no regard for a users learning needs or preferences and pedagogical theory. If the learning theory is not taken into consideration, the lack of regard for an individual's learning style could cause a student's discomfort level to be great enough to hinder or prevent learning (Felder 1996). The constructivist theory introduces the idea of how the learner is intrinsic to the learning experience. Learners construct knowledge by making sense of experiences in terms of what is already known (Brandt 1997). A learner's objectives, pre-knowledge, and how they learn – their learning style or preference – is therefore fundamental to how the learner will retrieve and map (to their frame of knowledge) any new information presented to them. As well as issues concerning the learner, there are financial and time considerations for the development of quality digital online learning content for the educational providers as they face a significant challenge in achieving return for investment (Marchionini, 1995). One means of optimising the return of investment is to facilitate the repurposing of learning objects across multiple related courses. Adaptive hypermedia systems (AHS) are aimed at tackling and overcoming these difficulties by customising courses to individual users despite differences in ethos, learning goals, pedagogical approach and a learners prior experience (Conlan et al, 2002). Adaptive hypermedia has the potential to break through traditional educational barriers by allowing the tailoring of applications to specific user needs and requirements by possessing a model of the user. Much of the focus in adaptive hypermedia for educational courseware has attempted to alleviate the difficulties of content comprehension (cognitive overload) and orientation (so-called 'lost in hyperspace' (Laurillard, 1993). Adaptive presentation techniques which effect changes to both the selection of different media depending on a users preferences and adaptation of the content based on an individual's user model are beginning to show success. Also the use of adaptive navigation which effect changes to the link structure between elements of the hypermedia courseware based on an individual user's (mental) model, has proven effective since learners using such systems have demonstrated faster learning, more goal-oriented attitude and take fewer steps to complete a course (Conlan, 2000). There is a two-tiered aim to this study: the corroboration of the premise that the design and delivery of educational technology should depend upon the pedagogic designs conceived by educators rather than depend on the characteristics of the technologies (or AHS) itself. And secondly, to explore the concepts of learning styles and their implications for the design and development of on-line distance education courses. Through this process some underlying pertinent questions will be addressed: Do individual learning styles have an affect upon learning outcomes in Adaptive Hypermedia Systems (AHS)? What implications could this have for AHSs? And to what extent is it possible to incorporate the principles of learning style theory into the design and delivery of personalized courses using AHSs?

The Study

The author approached this difficulty from the position of the instructional developer, identifying and cultivating the learning styles of an SQL class using a VARK inventory for learning styles, and adapting a framework that has been created by a computer engineer for personalized learning by modelling information to allow for Learning specific content. The Adaptive Hypermedia service to be adapted for learning preferences and styles is at present being successfully employed in the delivery of undergraduate degree courses at Trinity College as well as being used as part of a major EU research trial (EASEL). The project aimed to create a mapping between the educational designer's expertise and the technical implementation of adaptivity by modifying three architectural models – content, learning and narrative – so that the current AHS can use the extra knowledge provided to enhance learning. Increasingly, the most important question being asked about the application of new technologies is - What is known about the way students learn via the new technology? Pedagogy should take precedent when implementing new technology and new educational technologies and Web based learning offers great potential in that there is a chance to learn from previous mistakes of previous technologies and develop new learning experiences for students that have not been possible before (Clarke, 1983)(Parson, 1998)(Alexander, 1999). Technology, multimedia and software can go a long way in filling the gaps caused by a dichotomy of learning and teaching styles but "…whether or not the processes of teaching and learning are enhanced by the use of ICTs depends more upon the pedagogic designs devised by educators than upon the characteristics of the technologies themselves"

(Kirkwood, 1998). The emphasis on meaning making has increased due to the influence of constructivist approaches to teaching, and in learning, much more emphasis is placed on personal meaning making. Students face the task of appropriating external knowledge and turning it into personal meaning. The advent of the web, coupled with constructivist views, places additional demands on students, lecturers, and the ways in which they process this particular web form of extrasomatic knowledge. The demands are pedagogical challenges and universities are showing increasing interest in pedagogy and are beginning to regard the web not as a delivery medium but as a potential teaching and learning tool (Fetherston and Cowan, 2001). Once the focus shifts from delivery medium to pedagogical tool, we can consider pedagogical constructs that can be applied to the use of the web shifting the debate from the technical issues (Fetherson and Cowan, 2001). Technology needs to be tempered with reference to sound pedagogical principles – we need to be reflective about the direction and nature of such change and to keep the focus on pedagogical concerns (Fetherston, 2001). Educators must be competent managers of learning experiences in order for learners to attain success. The message should be clear to the learner and the medium should convey the message with interest, accurate perception and effective learning (Blanton, 1998). During the course of this study, a literature review was conducted on learning styles, Adaptive Hypermedia Systems (AHS), and instructional design models. The author aimed to elucidate the design of an artefact and explain how it was influenced strongly by the literature reviewed. Throughout, the main thrust of findings is derived from the design, rather than the development and implementation of the project. Final implementation of this project is due to be carried out in the future on a Java course.

Findings

An individual's personal learning style describes the way in which they habitually approach or respond learning tasks presented to them (Riding and Rayner, 1998). Although learning styles theory has become very popular over the years, it is far from being universally accepted as a theoretical construct. There is a glut of research on learning styles but there does not appear to be any widespread agreement upon, or acceptance for, any one particular theory to measure individual learning differences. Educators are becoming increasingly aware that if different people learn in different ways and individuals' preferred learning style influences how best a learner learns and as a result some aspect of learning style theory must be considered when designing, developing and delivering instructional processes or programmes. Motivational and learning strategies are also crucial aspects of self regulated learning. Learning "strategies" are often discussed as an integral element of learning styles but must not be confused with the "styles" themselves. "Style" has a psychological basis, it is relatively permanent state for the individual, and it refers to the way in which a person thinks. Learning Strategies on the other hand are behaviours or methods that learners use to improve their understanding, integration and retention of new information in the learning process (Cross and Steadman, 1996). Self-regulated learning involves use of motivational and learning strategies to the degree that students are motivationally, metacognitively and behaviourally active participants in their own learning processes (Zimmerman, 1989)(Pintrich, 1995). The instructional design approach taken took its cue mainly from a constructivist approach which emphasises the interpreted and individual nature of knowledge (Duffy and Jonassen, 1992) while keeping in mind that the web can be used as a teaching and learning tool because it can support social constructivist approaches to learning (Fetherston, 2001). Within Trinity College the approach to implementing an adaptive education system undertaken by (Conlan et al, 2002), is to provide a generic model for integrating the learner model (which describes the pertinent learner characteristics), content model (which describes the pedagogical qualities of the content) and the narrative model (which describes a mechanism for combining the content to produce a coherent educational courseware component). The adaptive engine within Trinity provides facilities for reconciling the Content, Learner and Narrative models to produce individualised content. This is achieved in a manner, which is independent of the content or the specific properties of the learner. This generic interpretation of how the Adaptive Engine interprets the models is central to its ability to integrate into different Learning Environments. XML is the key technology used to describe the models and it is the association and reconciliation of different XML elements in the models that is the responsibility of the adaptive engine. Key concepts in the adaptive engine are candidacy and abstraction. Having multiple candidates that fulfil the same learning goal enables the systems to choose the most appropriate candidate, for the learner, at runtime. The system must, however, have criteria upon which to base the selection. The information upon which the selection was based is characterized in the metadata. A VARK inventory was used as a guideline for creating a descriptive framework for producing this metadata. The VARK inventory is widely used in educational institutions around the western world and has received high acclaim from students and professors for its simplicity [http://www.vark-learn.com/wwwboard. It appeared to make good intuitive sense to both those educators and learners who used it and it was easily represented in the metadata. Though it is intended to explore the potential of VARK and other learning styles as selection criteria in future studies. At the outset of designing for a AHS medium, the instructional designer should strive to consider all the variables of the instructional environment would result in more effective instruction. It is not sufficient to just know what content is suited for learners; it is equally necessary to know how to present this content in an appropriate way. To do this the preparation of content involves selecting and organizing data, i.e. defining a planned structure consisting of subsections, itself able to be broken down to its most basic level (Labour et al.). Or in this authors case, it meant examining the existing content and investigating how the current models (content, learner and narrative) could be adapted for individual learners. The current metadata will be adapted so that all the models will be more focused on pedagogical elements. This pertains to how the Adaptive Engine can combine the models to provide effective and coherent course material to the learner (Conlan et al, 2002). For the online paradigm, as in traditional classroom situations, there is no consensus on how best to model the learner's preferred approaches to learning. There tends to be a clearer separation of the learner model and content model in AHSs (as opposed to the integrated approach of ITSs), and the narrative (or pedagogical) model is usually either embedded in the content or into the adaptive engine. This means that applying new or different pedagogical models, e.g. case based learning, simulations etc., to the content model is more difficult and involves a re-authoring of the content model. This results in learning content that is difficult to reuse or an engine that is domain specific. But the AHS in question has a multi-model approach, there is a clear separation of content, learner and narrative models, and a generic adaptive engine that employs a multi-tiered Artificial Intelligence model to achieve effective adaptation to the learner's requirements (Conlan et al, 2002). This separation improves the possibilities of reusing a piece of learning content as the learning object (LO) is no longer specific to a given implementation or narrative model. The second goal and advantage (with respect to content) of this approach is to allow course designers to easily discover appropriate learning content in the content repository. This is facilitated by two mechanisms:

- Creating the appropriate descriptive metadata for the various chosen learning styles.
- Free text searching, i.e. enabling the author to search the raw learning objects.

BEST COPY AVAILABLE

The approach is to have no semantics actually embedded in the adaptive engine itself. Therefore the pedagogic semantics that govern the narrative sequence of the learning experience are contained in a separate model. The adaptive engine then reconciles the three models to compose, at runtime, the personalized course. This approach enables multiple narrative models to be constructed to fulfil different learning goals, while these goals may be achieved from a common repository of content. The current AHS (called the Personal Learning Service) produces dynamic content (content created on the fly) for the learner based on run-time properties (the way the learner is connected to the network, prior knowledge). The intended outcome of the study is to provide a descriptive framework or mechanism for describing content already produced. The population and execution of the amended PLS is currently being completed with the assistance of the original innovation team that created the PLS. This author's role (from the Instructional developer's perspective) was to manipulate or rearrange the content of each pagelets for the Learning Model, Content Model and the Narrative Model in an a attempt to create a framework for re-useable learning resources to support personalized learning based on the learning style of a learner. By modelling the information to allow for Learning Style specific content the PLS can then use the extra knowledge provided to enhance learning. The necessary metadata information for describing both the learner and course model was identified after examination of the literature available. A descriptive framework based on pedagogical rationale was created to justify the metadata chosen to represent the attribute. Various learning styles and preferences as well as instruments for testing were examined. They were considered on two accounts; firstly, could they make a pedagogical impact on the narrative selection (Gregorc) and Content (VARK) and secondly, it was examined to what extent could they be represented in metadata. The decision was made to use the VARK identification system as a candidate selector for the content model, though after more thorough testing it should be more apparent whether any identification system could be used. The rules and narrative structures were investigated for how they would support the Gregorc model for the Narrative model, (but it was not intended at this stage to extend the narrative model). From the examination of the literature available, decisions were made for the optimum metadata attributes best used for determining course content for VARK. There was a need for a descriptive framework to render the structure or layout in which the content is placed (Narrative model) and the type (or format) of content displayed (Content Model). It was also needed to assist the computer engineering team involved to re-use the present learning resources and extend the models for visual (V), auditory (A), read/ write (R), and kinaesthetic (K) learners (see Appendix A, D and E). The architecture models – content, learning, narrative were modified according to this descriptive framework, so that the AH engine could use the extra knowledge to enhance learning. Throughout the process, the author considered how difficult it could be for the non-technical person (for an educator) to create such a descriptive framework for any kind of learning style, and adapt or develop content for a model-based AHS, and then populate it and execute it. The PLS enables many candidate narratives, (supporting different pedagogical approaches to structuring the content), to be associated with a single course. This association and an appropriate selection mechanism enables the PLS to deliver a personalized course that, while dealing with the same subject matter, can be structured in a way that best engages the learner's preferred learning styles. The subject matter, however, is not referred to directly in the narratives, but rather through the mechanism of candidate content groups. The instructional designer used this mechanism to implement several candidate pieces of content. Each candidate can be designed (against a set of informed criteria/rationale based on pedagogical considerations and outlined in the descriptive framework) to best support a learner's preference for how the content is presented. At runtime the PLS can determine which candidate is most suitable. Such factors under consideration were how the Instructional designer could decide upon specific content and then develop it for a model-based approach and how this rationale could be interpreted by both the AHS designer and instructional designer. The learning model determines the narrative model, and sets of narrative model content determine the content model. Also a solution has to be found whereby content suitable for a combination of learning styles could be produced for the "multi - modal" learner. A flexible Narrative model would allow for the learners content to veer into each of the styles. A series of problems are posed: How does one express the drift between various learning styles and what logic or rules can be used to describe or define this i.e. how to define A pure, B pure, C pure or a combination of AB, BC, AC. How can the midpoints of learning styles AB, BC, AC be identified for the narrative model or having identified the fixed points, how to focus on the way that A drifts towards each other learning style (B, C, D). Currently there are no guidelines in existence to aid the instructional designer in developing such a framework.

Imagine the learner with a VARK of V=2, A=1 R=1, K=3. This represents a learner who is quite strong visually and enjoys interacting w/ L material to learn. The descriptive framework (see Appendix D), developed as the artefact, has been used to describe a number of pre existing learning objects. These objects both deal with the same learning concept using different rendering. In this case the concept is the for loop in Java and is rep by a flash animation in one learning object (candidate A) and example code and explanatory text in the other (Candidate B). Their respective VARK values are :

Candidates	V	A	R	K
A	3	1	1	1
B	1	0	2	1

Candidate A is characterised by a strong V score. It also has A and K scores that rep a small amount of audio feedback accompanied with some basic user interactions (such as stepping through facility). Candidate B has a strong R score representing the material in varying forms: code and accompanying textual explanation. It has a zero score for A, as it does not contain auditory content. Its V and K score rep the interaction the learner may have w/ the material as they re-read the concept too understand it.
The AHS must determine, at runtime, which candidate is the most appropriate for the learner. As stated in (see 2.5) one of the advantages of VARK is that it is an intuitive representation. This intuitive knowledge, however, must be expressed in a way that the AHS can make a qualitative decision. This expression is rep as a subset of rules that the system uses to compare the candidates and the learner. The algorithm used for this comparison is based on "Pearsons' correlation" and compares the highest Two VARK values of the learner [http://davidmlane.com/hyperstat/A34739.html]. Where there are more than two values that are the same or higher, the top two are selected in the precedence order RVKA. THIS IS due to the fact that online education systems, and the content they deliver, are traditionally stronger in the delivery of visual and textual content. This precedence order may be adjusted for systems with more auditory and kinaesthetic content, for example. In this case a Pearson's algorithm selects candidate A for the learner. This process can be repeated for as many candidates that exist for a given concept. The key to this process is not the selection algorithm, but the criteria used (according descriptive framework, see appendix IV) to describe the content.

Conclusion

This paper examines the pertinent pedagogical principles that influence both structuring of courses and the selection of learning resources. The artefact produced from this work is an instantiation of those principles with respect to the VARK learning preference. The methodologies employed can be transferred to other learning style and preference considerations. The two most important aspects of these methodologies are that the instructional designer can maintain pedagogical integrity and integrate those principles with the existing adaptive educational system (in this case the PLS).

The artefact developed, coupled with the model based architecture of the PLS, provide a framework in which the instructional designer and HS developer can produce pedagogically sound personalised educational systems that maximise content and structure re-use. The key aspect of this work is that the technology is supported by re-useable pedagogical components – be they alternative narrative sequences or different renderings of learning concepts.

Introduction

This contribution is mainly based on our research, evaluation and experience within the project "Virtual Operations Research/Management Science" – "VORMS". The virtual learning environment (VLE) VORMS is still in development by a consortium of six German Universities. The VORMS consortium works together closely with the European project "Operations Research World" – "OR-World", which involves Universities as well as enterprises from three different countries.

Within VORMS the educational institutes work together sharing multimedia learning elements over the Internet. These learning elements have a very detailed granularity and can be put together in various combinations, e.g. to build a full online course. They can also partially be integrated into traditional presence courses. Within this context they extend the traditional course over barriers set by time, place and interaction capacities of teachers, e.g. within a lecture.

Learning experiences and didactical settings within VORMS can be diverse, depending on which approach the student chooses. Learning online most frequently implies communication – varying from synchronous to asynchronous and from group settings to single person settings. A main goal of VORMS is to enhance technology-supported collaborative learning by designing and evaluating structures, which enable *effective* synchronous and asynchronous communication within a VLE.

Communication –a variable within a learning process

Studies evaluating the role of technology and technological support in learning processes have resulted in conflicting results. It is almost impossible to connect benefits in the learning process to one single variable. Usually, results specify diverse variables, such as educational strategy, technology used, content selection, qualities of the persons in the learning process and didactical style used (see [Hesse 1997] and [Keil-Slawik et al. 1996]). Research within VORMS does not add another study to the already conflicting results, trying to isolate one variable, e.g. online communication, and prove its importance. We assume that collaborative learning is a substantial part of a blended learning approach. Collaboration can only take place, if communication takes place (see [Siebert 2000]). This demonstrates the importance of communication as an aspect of learning.

Online learning – online communication

Didactical beliefs concerning learning settings are changing over time. These changes often result out of innovative, new technologies. Besides offering time and place independent learning possibilities, technologies are focusing on customizing learning material as well as integrating new communication possibilities specifically designed for use within virtual environments.

Currently, the trend which can be observed within electronically enhanced learning is moving towards the direction of blended learning. Blended learning implies that already known components of virtual and traditional methods, concepts, and didactical beliefs, both used in isolation or in group work, are being put together to offer a holistic learning experience to the students. This typically integrates virtual study phases, traditional presence phases and settings where students learn alone or in groups – both virtually and/or traditionally. A holistic learning experience, when looking at it from a moderately constructivist angle (see [Siebert 2000]), substantially builds on collaborative learning. When promoting collaborative/cooperative learning, it is important to integrate research on communication theories, to evaluate if models designed for traditional settings are still applicable within web based settings or if they need to be adjusted or rebuilt completely. While ICTs continue to develop and grow, they capture more and more areas of our everyday life also influencing traditional communication. Current communication settings are changing at a tremendous pace. Communicating face to face is still done by almost all of us, but the use of email, chat, short message system, electronic discussion boards, white boards and the internet in general are expanding rapidly. Being reachable almost everywhere synchronously with cellular phones has become just as self-evident as asynchronous communication possibilities e.g. emails to persons on a different continent, arriving within seconds. Discussions within newsgroups also facilitate asynchronous discussion possibilities, and due to the nature of the medium complete discussion threads are traceable as long as they are online.

Defining success and defecting factors of communication online within technologies require the use of communication theories. The communication model of Friedemann Schulz von Thun (see [Schulz von Thun 2001]) describes that each message sent, and each message received is enriched with usually one of four aspects. These four aspects are:

- Content
- Relationship
- Appeal
- Self revelation

A sender encodes a message into verbal speech. He sends it, and the receiver decodes and interprets it. During a communication process between sender and receiver disturbances may take place while the message is en- and decoded. Disturbances can occur both on the sending and receiving side – and are due to the fact, that sender and receiver can give messages more than just one single meaning.

As our research shows, defective communication frequently occurs within online communication. Success factors for effective communication can be derived and generated when analyzing these disturbances. Conducting qualitative research, e.g. with a guideline interview within this area is extremely generative to receive empirical data describing success and disturbance factors. This qualitative, empirical method gives the interviewees the freedom to express what they really mean, describing it in their own words, without being pressed into predefined categories (see [Koenig 1999]).

Success factors for communication online – results of an evaluation

The evaluation was conducted qualitatively, by interviewing students. They had taken part in a course, where virtual communication possibilities were used to supplement the presence phases. The empirical method of the guideline interview was used to ensure the assessed data is reliable and valid (see [Koenig 1999]). Some aspects were also assessed quantitatively through questionnaires.

Natural communication

Our evaluation shows, that offering communication possibilities to students which seem "natural" to them is a key success factor for communication online. Natural electronic communication seems to be a contradiction itself. How people use technologies and if they accept them as being "natural" depends on their prior experiences with the medium. While some groups of persons, mainly older generations, may have difficulties getting used to the use of e.g. cellular phones, e-mail, or internet in general it seems that the younger generations make use of many of these possibilities. Accepting new technologies as being "natural" can be stated, when an integration into everyday life has taken place.

Knowing who the VLE is being developed for is essential when deciding which communication possibilities are going to be integrated. Analyzing the target group concerning their affective, situative and cognitive affilitiations (see [Euler 1992]) towards the use and acceptance of new technologies, and communication, is a main success factor when developing a VLE.

Analyzing the target group of VORMS shows that there is no student who does not have an e-mail address. In a questionnaire passed out to them, the majority stated, that they have made prior experiences with doing researching on the internet. Most of our students have been involved in a discussion database and most all of them have chatted before. These technological standards which were assessed in the questionnaire were also mentioned in the interviews to be natural electronic communication for our target group.

Mobility

Our students visit our website frequently, which can be seen in the number of visitors, but also in the online registrations for courses. Almost all of our students own cellular phones. These prerequisites make it clear that mobility is a factor, our students don't want to miss out on. This can also be seen in the desire to learn independent of time and place. Offering mobile communication possibilities is important for the success of our VLE. Additionally we offer our students the possibility to work on different computers and when logging on to a file server, their customized learning environment, including personnel notes and bookmarks is retrieved. Students want to increasingly learn where they want and when they want. Integrating asynchronous communication possibilities is another way to support these aspects. Synchronous communication e.g. a chat function makes it possible for learners to see which other learners are currently online, and if they wish, they can get in contact with each other.

Communication rules

Integrating communication rules into a virtual setting enhances the communication within a VLE. When students communicate with each other traditionally, certain rules are internalised and applied. Online communication does not have a history long enough so that there are general rules everyone knows. Students described that depending on prior experiences rules may also vary. To avoid misunderstandings resulting from unclear rules VORMS integrates a phase into the presence courses, where the students make up their own rules and guidelines for discussion on the web. Some groups make more rules than others, some make no rules at all – it all depends on the students and the group dynamics involved.

Goals

The students studying with learning elements constructed in VORMS prefer a learning setting where all students involved in the learning process have one common goal, preferably also the same time schedule to realise this goal. Communicating with each other is enhanced, e.g. if there is a test coming up for all of them at the same time. Our evaluation has shown, and the students interviewed approve of this fact, that communication intensity increases as the test comes nearer.

Personnel contact

Our students state, that when being personally acquainted to the people on the web, misunderstandings do not take place as often, as if they did not know each other. This is another reason, why we are combining presence phases and virtual study phases to supplement each other. Difficulties with encoding and decoding messages (see [Schulz von Thun 2001]) seem to be even larger in VLEs than in traditional communication settings.

Conclusion

Continuously developing online communication is a new approach towards the extension of traditional hypertext systems. Communicating effectively within VLEs creates new didactic and design conflicts, which have to be handled in a systematical and well-founded way to gain from their inherent creative potential. Empirical research is needed to describe the momentary circumstances encountered, when trying to communicate online. The main goal of our research is to acquire the necessary knowledge and to develop a theoretical foundation. We have the basic architecture for this within VORMS, which allows us to realize and evaluate a variety of different types of communication possibilities.

Abstract: Socio-cultural approaches to research and design in computer-mediated communication and education suggest a unifying framework. Overall, research and practice in the area has suffered from a lack of coherency and usability, despite brilliant individual contributions. Socio-cultural approaches focus on action as the unit of analysis, uniting individual and social processes, and on how artifacts mediate between individuals/communities and their goals. They take into account the distributed nature of communication, knowledge, and communities, and have the potential to unite many in CMC from diverse disciplines with a range of interests, from the individual to the social, from the theoretical to the applied.

Introduction

Computer-mediated communication (CMC) holds promise to support distributed knowledge- and community-building in education, but research and practice in the area has tended to lack coherency and usability overall, despite brilliant individual contributions. Research and design influenced by socio-cultural perspectives offers a unifying framework. This paper presents a literature review highlighting work helpful in that pursuit.

Perspectives

Problem: Critique of CMC Research and Practice in Education

Research and practice applied to education has tended to lack both coherency and usability on broad levels. The boundaries of the area have not been defined. For example, how does the area of CMC relate to that of distance education (DE) or cyber-culture studies? Researchers and practitioners have emphasized the unique nature of CMC and the need for new methodologies. Relevant research in related areas has been largely ignored. For similar criticisms see Burge 1994 and Gunawardena 1997. The study of CMC and education encompasses many from vastly different disciplines, yet there is little debate concerning methodological stance.

Researchers in the area rarely synthesize the literature in an interpretable way that pays respect to the relationship between research and practice. Those syntheses that exist tend to be either purely quantitative, excluding the majority of work in the area or, in contrast, are practitioner-oriented syntheses of best practices drawn from disparate 'research'. This latter critique is applicable to even well-conceived syntheses that provide admirable guidance to the practitioner (i.e. Harasim, Hiltz, Teles & Turoff 1995; Palloff & Pratt 1999).

To some extent, these problems reflect the early times in studying CMC, and the inter-disciplinary nature of the pursuit. Nonetheless, they indicate a need to reflect systemically upon our approach. Silver (2001) suggests that the study of cyberspace has only recently entered a more thoughtful, less enthusiastic stage. He links the recent more tempered, critical approach with a consideration of methodological approaches, and a return to tried-and-true methods rather than re-invention of the wheel. Efforts by researchers to modify methodologies to suit the information age may facilitate the development of integrated approaches to CMC research and practice in education. Eisenhart (2001) suggests that ethnographic methods applied to education will have to be modified to suit the information age. For example, the definitions of community and of participant observation will have to evolve to allow for sites that are distributed across place and time. Contrast this perspective with early criticisms of Rheingold's use of the term virtual community in 1993 (see Rheingold 2000).

Socio-cultural Perspectives: a Possible Solution

Recent research in CMC and education demonstrates that socio-cultural perspectives (cf. Vygotsky 1978; and also Cole 1996; Engestrom 1987; Wertsh 1995) hold some promise as a unifying framework. A socio-cultural framework shifts the unit of analysis from the individual to action (acts within context), uniting individual and social processes. Socio-cultural approaches can encompass diverse multiple perspectives, making room for individual and social processes, and how they inter-relate within the context of an activity system. Salomon (1993) argues eloquently that an analysis of the individual remains important in distributed, socio-cultural views. They try to account for the role of mediating tools between individuals and their goals, and for the distributed nature of knowledge, communication, and communities. They focus on artifacts and their role in activity. Socio-cultural approaches appear especially suited to the unique characteristics of CMC, which has the potential to support distributed relationships, community, and learning.

Vygotsky (cf. 1978) focused on an analysis of the mutually constitutive relationship between humans and their world through mediated action. He believed that thinking and memory develop through a dialectic process where the child is affected by the world, but also changes the world, through cultural signs and tools. Higher psychological functions do not develop simply as the organism matures biologically, but rather depend on the dialectical process of change that the child engages in through mediated action. Cultural tools and signs (artifacts) mediate human action. These ideas permeate socio-cultural perspectives: Cole (1996) suggests that the idea that artifacts mediate action is related to Geertz's argument that culture acts as a controlling mechanism.

Just as Vygotsky applied a dialectical approach to history to his study of the higher psychological processes, he applied it to his research methodology. His research methodology focused on process rather than performance, since the focus of study is on change, that is, it is *historical*. Also, he focused on observation of subjects. As in experiments he would intervene in order to allow one to see processes normally invisible.

Wertsch notes that an important question has been where to give analytic primacy, to the individual or society? He believes that socio-cultural researchers must transcend the individual-society antimony debate, taking action as the object to be described and interpreted; action is the context in which individual and society are each understood to be "interrelated moments" (p. 60). A focus on action unites the study of individual and social processes. Several approaches to analyzing action exist (Cole 1996; Engestrom 1987).

Applications of socio-cultural perspectives to CMC design

Brown and Duguid (1991) suggest that CMC may function as an artifact that supports organizational learning. The mutually constitutive relationship between artifacts and the users is key. CMC systems can be used to bring newcomers into the community (tools affecting users) as well as provide users with the means to adapt the tool systems themselves to match their own values and goals (users affecting tools). Old-timers may have previous conversations or products that newcomers can view. Newcomers will themselves provide content eventually.

Viewing CMC systems as artifacts might help designers support a mutually constitutive relationship between the students and the system. Participants in online discussions naturally construct much of the content of the learning environment. Designers can make more explicit students' natural contributions to the online environment. Participants can also be enabled to contribute to the environment in a myriad of ways, including: summarizing class discussions (i.e. Hara, Bonk & Angeli 2000), creating personal links between messages, collecting resources for class use, and contributing finished projects for future classes (i.e. Giordano 1998).

Some (i.e. Clancey 1997) have focused on more direct involvement of participants in the design process to promote their feeling of responsibility for the building of artifacts in the learning community. Clancey argues that an activity-based perspective places the emphasis upon the social ("activites are inherently social") making it important to address issues of membership, participation in a community, and identity. (p. 284) He promotes participatory design of computer-based environments, where tool designers, workers and researchers collaborate together, and it is the practice of the users that provides orientation.

Knowledge Forum was developed following situative perspectives (Hewitt & Scardamalia 1998). A variety of interface features aim to support knowledge-building. Students directly contribute to the artifacts that the community is building by contributing online. Students can build on other messages or annotate messages. When referencing other participants' messages, they can choose from a pull-down list that includes all messages. Students can mark notes as potentially for publication. They are able to view messages from multiple perspectives, and to choose different types of scaffolds to support their communication.

Applications of socio-cultural perspectives to CMC research

Gunawardena, Lowe and Anderson (1997) take an interesting methodological approach to studying asynchronous online debates amongst professionals. They advocate analyzing each online activity as its own totality. They analyze two online debates by examining the changes underwent by each 'community of learners.' They describe key phases each group experiences in the co-construction of knowledge over two weeks of online discussion. Their approach is radical in not providing room for an analysis of individual processes. Its strenghts are its potential to measure learning of a distributed nature, and the contextualizing of the methodological approach with reference to that of others in the field.

Giordano (1998) applies socio-cultural perspectives to her design and methodology. Students viewed design projects produced by prior students, and any attached comments and/or reviews, in an electronic repository built in Lotus Notes and accessible through the Web. They added their own projects, while documenting the ways in which they adapted or adopted design precedents. They also contributed reviews or comments. Methodologically, the shared design memory created through this sharing of cases and discussion is viewed as part of a distributed system. To explore the impact of the shared memory on individual and organizational learning Giordano considered dimensions related to three elements: the community of learners, the shared design memory, and the design artifacts. To explore trends across the whole community of learners specifically related to the shared design memory, final designs were compared across three cohorts of learners.

Possible Frameworks for CMC research and design

Lewis (1997) presents a framework for exploring technology-mediated distributed communities. He draws on Engestrom's (1987) description of the structure of an activity: a triangle joins three elements – an individual who is helped by tools to achieve an object. This triangle expands to the community level by adding rules and division of labour. Lewis takes the nodes of this figure as a structure for his analysis, considering in turn various triads of nodes. For example, the triad of subject-tools-community encompasses issues of choice of media and collaborative tools, and the design of groupware.

Rogoff's (1995) framework of three levels of focus for socio-cultural activity could help frame CMC research and design issues. The community plane focuses on the institutional context and the role of cultural technologies. It would include explorations into the inherent and potential constraints of CMC systems in general and the role of CMC in the wider community in which the student is participating. The interpersonal plane focuses on the learning that occurs among people, so would include the learning experienced by groups or entire classes. The individual level focuses on how individuals are transformed through participation, so would encompass the kind of research most common in education.

Conclusion

Design and research influenced by socio-cultural perspectives suggests a unifying framework for the area of CMC and education Socio-cultural perspectives focus on action as the unit of analysis. They focus on artifacts and how they mediate between individuals/communities and their goals. They appear especially suited to the unique characteristics of CMC. Each application to CMC presented in this literature review provides some hope for the future of CMC applied to education, suggesting ways a researcher or designer can meet the challenges facing us as we explore and build distributed knowledge communities.

Using Virtual Web-Enabled Technologies and Design at Accenture to Enhance Entry Level New Joiner Training.

By Sandra Burke (sandra.m.burke@accenture.com) & Melissa Noonan (Melissa.noonan@accenture.com), Accenture.

In a company where human capital and expertise, and retention and cultivation of this expertise, is strategically imperative to its long term success, Accenture is charged with training up its entry level new joiners in the skills needed to be successful in their work with clients on engagements. The Professional Development Program (PDP) - Client Engagement Readiness program is tasked with training up these new joiners. Delivering effective training is a challenge considering Accenture has offices in 47 countries worldwide with new Joiners coming on board throughout the year. The program itself consists of 2 weeks training in local offices and two weeks classroom training in the U.S. Implementation of the local portion of the program varies. Traditionally, the local office portion of the program was delivered using binders and CD ROM self-study programs. There may or may not be faculty facilitators for the course depending on the number of participants and faculty availability. In a local office, there may just be one to two people joining the program, or a large start group. And skills and educational backgrounds of New Joiners can range greatly.

Today, however, a new local office training approach is being piloted using the capability of the web, e-learning, collaborative technologies, virtual coaching and event driven personalization to customize and improve the learning and user experience during the local portion of the program. The new program: 1) Provides access to expert coaching support synchronously and asynchronously via a number of delivery methods – like instant messenger, phone, email etc 2) Encourages peer-to-peer connectivity, communication and support across offices – using contact list information garnered from learner, and coach intervention to encourage individuals to work together 3) Customizes learning experience through use of self-assessments\diagnostics – to determine where to start in a self-study for example, or determine what path through a self-study to follow 4) Offers a broader range of learning experiences\training product options\opportunities depending on learner's needs\diagnostic results – for example offering additional training options for those needing more baseline skills, or those needing to stretch their learning 5) Improves content delivery – providing learner with recent content updates, status of issues \errors, and additional content materials like answers to frequently asked questions, and presentation materials with faculty notes etc to overview of reinforce key concepts etc and 6) Enables program sponsors to craft and deliver customized communications to learners based on their program enrollment status.

This paper discusses these new program features and the findings from recent piloting\testing of these features with learners. Future directions of the program are also discussed. These include: 1) Self serve download of key course software (self studies), 2) Introduction of self check questions and tracking to monitor performance and learners location in program 3) Use of that information to offer coaching feedback and remediation and finally, 4) the potential to extend the coaching role to provide local faculty with support to ensure consistent delivery of the course.

Independent Study based on the Strategy of Online Workshops to Develop Professional Abilities (TDHP) of UNITEC

Abstract: The present study reports an analysis of a procedure to develop online workshops for undergraduate students. Furthermore a methodology to generate specific interaction between the participants and a previously prepared content, as well as specific student-tutor, student-student interactions that favor adequate attitudes towards online education is proposed. The result conclusively show that the strategy accomplished a fluid and effective learning experience for the participants with regards to the workshop's contents. Additionally, the workshop promotes a favorable interaction between all members of the online community. Of special importance is the fact that students developed a life long attitude of continuing self-education. We conclude that the proposed methodology for the online workshops effectively complements educational processes for undergraduate students in Mexico and that it is an excellent tool to enable continuous education.

Alfonso Bustos Sánchez, Beatriz Yolanda Jiménez González, José Ignacio García-Santamarina Vite
Instituto de Investigación de Tecnología Educativa
Universidad Tecnológica de México
abustoss@mail.unitec.mx

Introduction

The INITE (Instituto de Investigación de Tecnología Educativa de la Universidad Tecnológica de México) has developed during the past years an educational program called Talleres de Desarrollo de Habilidades Profesionales (Development of Professional Abilities Workshops) aimed at undergraduate students. Some of the topics presented at the workshops include: Business Consulting, Interpersonal Relations, and Self-Education, among others. This last workshop has been defined as a workshop that reinforces the educational process in the college years and creates a motivation to continue this process through life. For three years, our experience with the workshops has been enriching and satisfactory. The results have been constantly monitored and evaluated and a progressive improvement has been carried out with the workshop activities and the student and tutor manuals. The communication with the participants has been both vigorous and constants, resulting in a steady stream of suggestions that helps us mature the workshop format, the time frames related to the different activities schedule and even some interesting suggestions related to the flexibility of the educational model used in the workshop.
Using these suggestions combined with our continuous research, and as a first step to explore the uses of Internet in UNITEC we decided to create a program that initially was thought of as complementary to the existing workshops. This program became the online format of the THDP being taught at campus. From the nine workshops that already existed on campus, we selected the Self-ed workshop and developed an online version. We took into consideration the following elements to support our decision:

1. The contents generate a significant learning environment that is highly motivational and self directed to "…fomenting the self- educating process directed to the forging of autonomous abilities and attitudes to achieve the optimal academic and professional performance (Autoeducación, 2000)." This said environment could be favored by an independent dynamic studying experience. One that promotes autonomy, self-regulation, collaboration, team work and, according to certain authors a studying model that more seems to favor the life long process of education: online off campus education (Abués and Tarín, 2000).
2. Another argument, supported by certain authors (Aretio, 1996; Duart, 200), is that last course students have possibly developed a better discipline, self- regulatory strategies and the necessary self-motivation to successfully participate in an independent training program than those students from the early studying cycles.
3. The Self- Education workshop is studied by ninth (last) quatrimester students. One of the mayor concerns regarding the online workshops had to do with the students' possibility of accessing the web. We discovered that last quatrimester students had a better chance of having both the adequate hardware and internet access due to the fact that most of the student population at UNITEC work and so have the hardware and internet access at their workplace and/or the economic means to afford one for home use. This increased the expectancy of studying and online workshop.
4. Finally the fact that most last quatrimester students are working was considered. Therefore an online workshop would have a huge appeal due to the fact that they could do the work from their own work places, and/or their home during their spare time.

Methodology of the Online Workshops

To speak of online education is evermore frequent. However, when an institution of higher education is analyzing the possibilities and implications of participating with this model, several issues have to be considered. Among the most important are:

- The type, amount and quality of technology that has to be incorporated into such programs.
- The processes of instruction of the faculty members and the selection of which faculty member should be incorporated.
- The different stages in which the technology and instruction of the faculty members should coincide to develop the educational program. The different stages into which technology is going to be incorporated.
- The institutional changes than this process bring on: First the impact on the faculty, the student body, the research bodies, the administrative staff. Secondly, the different regulatory, proceedings processes that have to be implemented.

Methodology

Based on this outlook, the strategy we outline, concentrated on the development of a methodology for online workshops that seek to establish itself as a complementary modality to the workshops taught at campus and to become the starting point to introduce new strategies and forms to the teaching-learning model.

Online Workshops Strategy

The THDP en Línea (Online Development of Professional Abilities Workshops) was defined as an asynchronous environment. This means that the Tutor-student, student-student, student-tutor is not simultaneous but parallel and/or syncopated. It is achieved by means of email and electronic forums that become debate centers on web pages. This facilitates the reading-learning process associated with the specific needs of the student at a particular time. Simultaneously, each student has the possibility, based on his/her access frames, progression rhythm and interests, to review the contents of the online forum and to participate when she/he considers pertinent.
The student has to provide an online activity that is also compulsory and that must be concluded with a written participation and/or essay in a forum. A certain complexity is inevitable regarding the student interaction in sending the information and revising existing and future participations of the other members of the community.
If a virtual community of 60 students has to develop (x) number of activities and as a final activity, each student has to write an essay with his/her point of view and recommendations for the workshop which is then submitted so that the rest of the members of the community can revise it, the complexity and amplitude of this process is so much more time consuming, enriching and formal than the same exercise in a classroom in a traditional sense, in which the opinions are often more punctual and less structured. An online community that promotes constant written production, we believe, favors the involvement of all members of the community and facilitates the interaction.
Activities that follow the **reading-opinion-reading-final essay** strategy, characteristically used in the first internet related experiences have proven their value generating and developing the online educational process. However the strategy no longer responds to the current virtual students and/or the potential in the new generation of web pages in which dynamic menus, interactive data bases and streaming multimedia have tap new limits of educational processes. A new strategy that combines the mentioned elements is more in the way of **reading-interaction with concepts-opinion-interaction with other members of the web community-reading-closing activity**. In this strategy, the reading can be a multi-platform, dynamic sequence of events that includes video, audio, reviewing and/or creating concept maps, crossword puzzles, and many more diverse didactic activities available on the web. This is the new strategy that defines the characteristics of the methodology in our online workshops.

Methodology

We developed the workshop on a LINUX platform, using as a primary tool for the student-student, tutor-student Hypernews ver.2.0. We also generated a system that would automatically register the student interactions (RAP-registro de alumnos participantes) using Posgress and PERL. This registry system links what our students are doing in Hypernews and tags an ID to the delivered assignments. Through this method, we have an accurate automatic report of the homework or papers the student is completing, facilitating the tutorial process and allows the tutor to concentrate on a quality interaction with the students. The tutors received special training sessions to gather in depth knowledge of the process and an online manual is also available to the students.

Javascript and Flash movies and in some cases digital video (.mov Quicktime) to generate the interaction thru concept maps, crossword puzzles, etc.. Most activities we drawn directly from the student's manual and then enriched with activities and contents from the tutor's manual. However, some activities were modified for the online modality based on two arguments: the activity could be modified favorably by online interaction through the addition of visual resources, data processing, immediate responses or the activity suggested by the workshop was too complex to be taken literally to the online process. The tools required were structured taking into consideration FACS, videos, two types of forums (exercises and essay), RAPs, interactive exercises and links to the web. (http://www.eva.com/Autoeduc/herramientas.htm)

The use of asynchronous forums was defined as the central axis so that each student could present his/her work and could receive feedback by the tutor and/or other students regarding his/her work. The primary task of the tutor was to review the topics discussed in the forums and to provide at least one participation to guide the discussion. A reading of the first and last essay submitted buy each student should also be read by the tutor and a personalize message sent to that student with specific comments regarding his/her work.

The online workshop consists of 4 modules, each with two forums, one containing exercises and a second forum for essays as a final practice. In total, each student should incorporate into his/her portfolio 17 papers: 4 short essays, as a conclusion for each of the 4 modules, and 13 obligatory exercises stating opinions on the forum for activities regarding the work done in each module. There are 5 other optional exercises. The workshop lasts two weeks in which no specific time frame is considered. The students can log on at any time and carry out any number of exercises depending on their time limitations, as long as they follow general considerations (http://www.eva.com.mx/Autoeduc/Recomendaciones.htm). To ensure this, the access system would not allow the passwords to open the workshop after a certain date.

Participants

The workshop was carried out with UNITEC students, structured around two groups, each one with its own tutor and its own time frame. A total of 92 participated out of which 19.5% belonged to the morning schedule, 54.3% to the evening schedule and 25% to the night schedule. 50% were female and 50% were male. 32% were students only, while 68% reported having a job besides their school activity. Most of the workshop population (64%) were majoring in Accounting, Law or Business Administration. Out of the remaining percentile, 36% were Economics, Marketing, Computing Administration, Finance and a variety of engineers (Chemistry, Electronics, Mechanical, Computer Systems).

Results

After a two week period, 84 students successfully completed the workshop, while 8 failed to do so. 41% of the students handed in 100% of the required work, 48.9% handed in between 9 and 12 exercises and only the 10.1% handed in less than 9 exercises. Regarding the essays, 73% of the students delivered 100% of the work required, 15% between 1 and 3 essays and 12% did not hand in any.

Regarding the tutelage done, several types of interaction were found to be developing:

Student-student: participants oriented themselves.

Do you think that the next generations will adopt this Self-education strategy?

1. Answer. Silvia Atescanco Pineda, Feb24, 16:23
    1. Marlene for Mariela Ramírez Uribe, Feb. 26, 11:15
    2. I agree Bladimir Peñafiel Campaña, Feb. 26, 18:31
    3. Answer: Juan Carlos San Miguel Ayala, Mar 01, 23:34

Student-Tutor: The student requests help from the tutor by e-mail.
Date: Feb. 19, 09:53
Author: Luis Rubén Espejel Parra *reparra*

"I study about a half hour every day and that has been enough for me, because I read what we do in class and even though it is very little (reading), I have certain practice already so it works for me and it allows me to know how much I need to (really) study. "

Forum: Module 1 – Topic 1
RE: Activity 1 (Luis Rubén Espejel Parra)
Date: Feb. 19, 10:19
Author: Tutor Frida Guerrero *fridagro*

"I think that in your particular case, studying is a habit which is very good and gives your learning continuity and when an exam approaches, you only have to review the acquired knowledge, facilitating your learning ability. Congratulations!"

Tutor-Group: The tutor sends group messages through the forums and by e-mail to provide information or to provide a single answer to a discussion line.

Question/Answers
Date: Mar. 08, 16:42
Author: Tutor Jaime Huerta *huerta*

"I would like to make public my appreciation regarding the participation, especially since it is so productive regarding the good quality of your contributions. (I) would like to exhort those of you that have not participated in the group discussions to do so as quickly as possible.

Regarding the questions and answers (I would like to say)..that the elements are directed mostly the professional need for constant self-education and training. This will give you the edge in an ever increasing competitive world."

Finally, we used a Likert type instrument to retrieve the students' opinions and we found that: 92% considered the feedback quick, 95% considered it more clear than confusing and 61% considered it to be very broad. 90% considered the exercises to be varied and broad. The tutor's response time was considered as quick by 89%. The forums were cataloged as user friendly (96%), useful (94%) and broad (95%). The essay forums were considered broad (95%) and user-friendly (97%).

Conclusion

The interaction between the students' and the self guided contents of the online workshop proved to be an adequate strategy to develop a self –education process. The high turn-in rate of the exercises and the high participation in the forums, indicates that the students could follow the planned sequence: reading-interaction with concepts -opinion-interaction with other members of the web community-reading-closing activity favorably. We can state that the exercises with specific, self interacting content allowed a focused activity, generated a process of opinion regarding the contents and finally developed a working space between peers and student tutor relations. At the same time, the high number of hand-ins regarding the final essays for each module show that the activity is an excellent option to comment on the learning experience for each module. This learning strategy, along with the contents of the online workshop and the asynchronous workspace shows the advantages of the tutoring process, thus guiding the student to an appropriation process of the knowledge from the online source. The social interaction accomplishes a significant role by focusing the learning-teaching experience in tutoring where the students' peers and the tutor serve as a guide more than a teacher.

Finally those that answered the pole, support our idea that the aforementioned work strategy does promote a favorable attitude towards a self-education processes mediated by computer hardware and software. Additionally it does generate easy to regulate, process and participate in a virtual community of self-education activities. Some aspects that need to be improved include automatic processes that feedback information to allow students to move at their own pace with a more efficient use of their resources (time, higher levels of participation in forums), the definition of evaluation processes that can truly measure the academic reach of the online workshops and a punctual follow up of the tutoring process.

The Impact of Learner Feedback on Program Redesign

Overview

T-PLUS (Technology for Principals Leading Utah Schools) is a technology-based professional development program for Utah principals and superintendents. Participants who complete the program receive the Advanced Certificate in Technology Leadership from Western Governors University and earn 144 relicensure points from the Utah State Office of Education. The $2,000,000 grant, funded by the Bill and Melinda Gates Foundation and the State of Utah, allows for 70 percent, or about 670 members of Utah's 949 public and private district and school leaders, to participate.

The purpose of the T-PLUS project is to support Utah's K-12 technology goals through a well-defined, state-coordinated technology leadership initiative that promotes integration of technology in district- and school-wide curricula to promote increased student achievement.

T-PLUS is designed around four primary goals:

- *GOAL I:* Identify and critique technology-supported learning environments that address instructional or performance improvement goals.
- *GOAL II:* Oversee and manage a technology-integration project team and its process, including providing for relationships among all stakeholders.
- *GOAL III:* Develop and justify strategies and tactics for introducing and integrating new technology tools and techniques based on change theory or a change model.
- *GOAL IV:* Design and complete an action research project either individually or collaboratively with one or more other participants. The project will be field-based, data-driven, and reflective of outcomes based on a technological intervention.

Design of the Pilot

During the pilot phase of the project, which began in January 2002, participants were given several options.

- Go directly to final assessments and take no coursework
- Take three instructor-led online courses based on the T-PLUS goals and objectives
- Take final assessments for some of the competencies while completing the remaining competencies via instructor-led courses

Since WGU does not offer courses itself, it contracted with other universities for three graduate courses to support the certificate program. Development entailed customizing the content of a similar course at the hosting institution to the goals and objectives outlined above and converting it to a format deliverable via the Web. . The synchronous courses were instructor facilitated and adhered to a standard academic calendar and format. Participants were required to complete assigned readings in a text and submit weekly assignments base on the readings. They were also required to take part in regularly scheduled online group activities.

Learner Feedback for the Pilot Phase

Within three weeks after the beginning of the online courses, participants began to fall behind or drop out completely. For the duration of the courses, participants expressed concerns about the amount of time needed to complete the weekly activities; lack of feedback from instructors on completed assignments; course content not relevant to their needs; technology issues; scheduling problems for participation in scheduled online activities; and overall frustration with their inability to successfully complete the program. By the end of the courses in May, the drop out rate had reached 60% and the end of course evaluations were extremely negative.

As a result of the increasing drop rate and participant feedback, in March the decision was made to redesign the courses for the Implementation Phase. The new design was based on participant input and lessons learned from the failure of the pilot.

Design of the Implementation Phase

The online course developed for the Implementation Phase is based on the four primary goals identified for the pilot. However, the design and delivery have changed dramatically. All academic content and scheduling are removed from the competency-based course. Delivery of the course is asynchronous and completely learner-directed. The participants are given a three-month window to complete the two modules, each of which can be completed in less than 10 hours.

The support materials for the modules include a CD-ROM, ***Principal Connections***; a practical guide to technology implementation, ***Planning into Practice***; and several websites related to the topics of the course. All of the materials have been reviewed by principals to ensure the relevancy of the content to the participants.

Access to the course has been simplified and the navigation has been designed to be user friendly. WGU mentors are assigned to each participant to ensure immediate response to problems or issues related to the course.

Learner Feedback for the Implementation Phase

Initial participant feedback to the redesign of the course has been extremely positive. Participants are now enthusiastic about participating in the program. They report fewer technology problems, timely feedback from mentors, highly relevant content; and realistic time requirements for completion of the courses. Participants have voiced their appreciation for the willingness of WGU to listen to their input and to carry out extensive revisions to meet the specific needs of principals and superintendents..

Combining Classroom and Online Approaches for Maximum Learning

Celina Byers, Ph. D.
Oakland University
byers@oakland.edu

Abstract: Working students attending long night classes are often unable to concentrate as the night progresses. An online course management system like WebCT can provide such students with resources that permit self-scheduled, interactive study to replace some class time. Online discussions, like classroom discussions, can be assigned, monitored, and participated in by the instructor, effectively creating a traditional course with a distance-learning component. Although this innovation meets strong initial resistance, students become engaged and declare it rewarding.

Introduction

Web-based instructional environments provided by course management systems (e. g., WebCT) can offer unique opportunities to design and deliver Web-enhanced courses, where we can practice what Owston (1997) suggests: "the Web can help us re-focus our institutions from teaching to learning, from teacher to student" (p. 27). Web-enhanced courses, because of combining face-to-face teaching and learning with Web-based activities, do not have the problems caused by the lack of a person-centered model reported by Miller & Mazur (2001). The instructional designer's major role, especially when designing and preparing courses for adult learners, is to provide an environment that stimulates active learning. However, having well designed material and well planned class activities is not enough when teaching night classes for students who have had a full day of work. There are many aspects to consider in order to extend active learning and nurture effective collaboration among students. Clear guidelines, specific due dates, constant monitoring by the instructor, and immediate feedback are some of these aspects (Horton, 2000). This paper reports on a successful attempt to replace the last 50 minutes of a 3-hour-and-20-minute classroom-based night class with online learning.

Scenario

Introduction to Instructional Design, in our Master's Program in Training and Development at Oakland University in Michigan, is a four-credit-hour course. The class meets once a week from 6:30 to 9:50 pm. Deciding what to include and how to deliver it so that the students will have acquired the necessary skills at the end of an introductory course of instructional design is always an interesting task because the elements necessary to be included fill every minute that the time frame of the course allows. Learning theories, for example, form a large portion of content that is an essential complement of Introduction to Instructional Design.

Because the introductory course of instructional design is four credit hours, it should allow enough time to cover all the necessary elements that need to be addressed. However, I realized early on that the students had a difficult time concentrating and participating in class activity after 9:00 pm. To solve this problem, I decided to replace the final hour or so of class time with activities that vary from the usual class discussion format.

Implementation

I was already using a course management system to make available for the students the course syllabus, the course assignment rubrics, class agenda, and presentations. We also used it for student-student and student-instructor communications. The decision to move the discussion of learning theories from face-to-face

BEST COPY AVAILABLE

to online seemed logical and easy to implement. We finished the class by 9:00 and complemented the instruction with online activities, activities the students could complete according to their own schedule.

To model the online assignment expectations for the students, I proposed and monitored the activities for the first three weeks. After that the students had the option of working in small groups or individually to propose and monitor the weekly activities. To set the stage, I made the first learning theory assignment active learning. The students were divided in groups of three and assigned to read three online articles on the subject. Then they held discussions within their group and defined the student and instructor roles in an active learning environment. They had available a private bulletin board forum, e-mail, and synchronous chat features to complete their group tasks. They had to compile and publish their group results for the rest of the class. The entire class then had a common online forum to discuss the results.

For each subsequent week they made a different selection from a list of learning theories that was made available for them to work on. The online activities varied for each weekly discussion. The students were given discretion to follow my lead in terms of the kind and format of activity or come up with something new.

At the end of each week an electronic evaluation form was made available so the students could evaluate their peers' performance. The grade for the activity was the average of everybody's input.

To evaluate the course development and intervene if necessary, the students were asked to answer weekly surveys with objective questions. They were also asked to provide a weekly journal in which they had to respond to three points and could make open comments. Close to the end of the course, they completed a capstone evaluation form, evaluating diverse aspects of the course.

Results

At first there was a negative reaction from some of the students. These people felt overwhelmed with the technology component of the course (which was not focused on technology). They brought their point of view to our question-and-answer time at the beginning of each class and voiced their concerns in the bulletin board discussions as well as any class moment that was possible. I was open to discuss any and all alternatives they could suggest. Each discussion about the use of the course management tool ended with the majority of the students agreeing either that they liked the class setup or were willing to keep trying to get more comfortable with the use of technology.

Before the middle of the semester, in fact, I had each of the initially reluctant students coming to me during class to say that they regretted their resistance because they were learning so much more and better since they did not have to force themselves to stay late to the end of the class period. Many of them told me that they were sure that would not be possible to have the same quality of learning if the same activities were performed in class.

The weekly survey results in which the technology use was assessed provided a quantitative measure that the majority of the group was in favor of the continuation of its use. The cumulative results of the survey showed that 80% of the group rated the use of technology positive, 17% rated it neutral, and 3% rated it negative.

Students also commented positively about their learning: "In terms of the learning behavior theories, I learned a lot. At first, I thought that the theory assignments were a necessary evil class requirement. However, I have changed my opinion of the value of the behavior theories. They can be very helpful to an instructional design. I think that this would be a very interesting class by itself. I understand why we need the Webct to finish the theories. Class time is too important for the instruction design concepts;" "Overall, I really enjoyed this class and support Oakland University using this course as a model of what all the courses should look like!;" "I absolutely loved this class. I have actually found it hard to focus on my other class as every time I sit down to homework I want to work on this project!. I will be spending the next two weeks playing catch up in there, because instructional design has stolen my attention for the past several weeks!"

On the capstone evaluation form, students were asked to indicate on a scale of 1 (lowest) to 5 (highest) their knowledge level, before and after taking the course, on some major constructs that were covered. Familiarity with learning theories (FLT) and with instructional strategies (FIS) were the two major focuses of the on-line discussion. On FLT, 58% rated their previous knowledge 1 and 42% as 2; 33% rated their after-course knowledge as 3, 50% as 4, and 17% as 5. On FIS, 100% rated their previous knowledge 1; 25% rated their after-course knowledge as 2, 42% as 3, and 33% as 4.

Discussion

In long evening classes that meet once a week, the concentration of students who are also full-time employees begins to lag before the end of the class period. An online course management tool can be a resource that permits self-scheduled study in diverse, interactive formats. Once the students have achieved the necessary technological skills, this approach appears to produce generally positive results.

To overcome the strong initial resistance to this approach, I recommend that instructors stimulate full discussions of problems students are having, engaging the entire class both in raising complaints and in proposing alternative solutions. Mature and open-minded treatment of students' difficulties, coupled with willingness to experiment with suggested changes, seems to lead to success. Above all, maintain a sustained course assessment process and be ready to undertake course intervention as soon as necessary.

Assessing Sense of Classroom Community in an Urban Community College Online Setting

Cynthia P. Cadieux, PhD
Tidewater Community College
United States
ccadieux@tcc.edu

Robert A. Lucking, PhD
Old Dominion University
United States
rlucking@odu.edu

Abstract: A self-report survey was used to investigate the sense of classroom community in an urban online community college classroom. Sense of classroom community scores were obtained as well as scores on four subscales of spirit, trust, interaction, and learning within the Sense of Classroom Community Index (SCCI). Differences between these five dependent variables and type of classroom setting (face-to-face or online) were ascertained by utilizing MANCOVA and ANOVA. It was concluded that sense of community was affected by classroom setting (face-to-face or online) and that learning may be enhanced by increased interactions within the classroom.

Introduction

This study investigated how classroom setting (face-to-face or online) affected student sense of classroom community in the online urban community college classroom. McMillan and Chavis (1996) state that community consists of four dimensions: (a) spirit - feeling that there is a community, emotional safety, feeling connected to others; (b) trust - feeling that the community can be trusted, and it is safe to tell the truth; (c) interaction - feeling that it is mutually beneficial to be in the community, one has a sense of shared values and those values are reinforced; and (d) learning - feeling a shared emotional connection in time and space arising from contact between the members of the community. A body of evidence suggests that a strong feeling of sense of classroom community is related to a more positive student learning experience and achievement gains (Bryk & Driscoll, 1988). These positive outcomes translate into lower drop-out rates, an increase in student-to-student referrals, and a deeper commitment on the part of the student to the institution and program of study (Biner, Dean, & Mellinger, 1994; Tallman, 1994). Rovai, Lucking and Cristol (2000) developed the Sense of Classroom Index (SCCI) to measure sense of classroom community as theorized by McMillan and Chavis (1996).

It is important to provide a positive learning experience in the online classroom setting as well. Asynchronous Internet instruction was among the top three technologies employed to offer distance education during the 1997/98 academic school year (U.S. Department of Education, 2002) and has grown steadily since, so the implications of providing a positive learning experience in the online classroom are great.

The Study

This study sought to answer the following questions using quasi-experimental methodologies:

1. How does the online classroom setting, utilizing a course web page, threaded discussion, and a course listserv, affect student perceptions of spirit, trust, interaction, and learning in an urban community college semester course?
2. How does overall sense of classroom community differ between students who drop out and those who do not drop out of courses in an online urban community college semester course, which utilizes a course web page, threaded discussion, and a course listserv?
3. How does age affect sense of classroom community of students enrolled in courses in an urban community college semester course, which utilizes a course web page, threaded discussion, and a course listserv?
4. Is there a relationship between overall sense of classroom community and academic performance in an online urban community college semester course, which utilizes a course web page, threaded discussion, and a course listserv?

Three hundred and twenty-one students from the two groups were included in the final statistical analysis, 248 in the face-to-face group and 78 in the online group. In addition, 42 students were classified as dropouts. The SCCI surveys were administered to both groups three times throughout the semester in which the student was enrolled. Surveys were administered to students enrolled in College Algebra and Statistics courses. A total of three face-to-face Algebra courses and three online Algebra courses were surveyed. A total of seven face-to-face Statistics courses and three online Statistics courses were surveyed. The same instructor taught all courses over three semesters. Online courses had the same course number as their face-to-face counterparts. Participants were those students who completed the course, received a numerical grade and completed the three surveys throughout the semester.

The Findings

BEST COPY AVAILABLE

The research questions were studied under the null hypotheses as follows:

($H_0$1) There will be no significant difference in perception of spirit between students enrolled in face-to-face and in online classes

($H_0$2) There will be no significant difference in perception of trust between students enrolled in face-to-face and in online classes.

($H_0$3) There will be no significant difference in perception of interaction between students enrolled in face-to-face and in online classes.

($H_0$4) There will be no significant difference in perception of learning between students enrolled in face-to-face and in online classes.

($H_0$5) There will be no significant difference in sense of classroom community between students who are classified as dropouts versus non-dropouts.

($H_0$6) There will be no significant relationship between sense of classroom community and subject age.

Course outcome was studied under the following null hypothesis:

($H_0$7) There will be no significant relationship in course grade between students who feel a strong sense of classroom community and those who do not.

The two groups (face-to-face and online) were made equal for all dependent variables using prescores as covariates. The MANCOVA model was utilized for statistical testing of hypotheses one through four. The researcher sought to discern whether the classroom setting (face-to-face or online) might have caused differing perceptions of the dependent variables. The independent variable was group (face-to-face or online) and the dependent variables were post-spirit, post-trust, post-interaction, and post-learning. The co-variables were pre-spirit, pre-trust, pre-interaction, and pre-learning. Results indicated that the main effect of group was significant for post-spirit, post-trust, and post-interaction. Due to significantly higher scores in the face-to-face group, the null hypotheses of no significant differences among the two groups were not supported for post-spirit, post-trust, and post-interaction.

The face-to-face group experienced stronger feelings of spirit, trust, and interaction at the end of the course than the online group. This finding may imply that the flexibility of the online environment might not lead to greater student satisfaction as suggested by some (Leidner & Jarvenpaa, 1995; Brandon & Hollingshead, 1999). The following explanations could be given for the lower scores in the online group: (1) Some students may define community as something that requires face-to-face communication. Defining community was not a focus of this research. However, the online students may not have even been thinking about values associated with a traditional sense of community during the course of the class. The reason for enrollment for these students could have been only for obtaining academic credit in a way that was convenient. (2) Perhaps some students enrolled in the online classes to avoid being part of a classroom community. Students may have participated only in those activities required for a grade and remained relatively silent throughout the course. (3) Students generally enroll in online courses due to the convenience of obtaining an education around a busy personal and professional life. Perhaps the students in the online courses were too over-committed to fully engage in the course. Therefore, the students could not or would not devote the time necessary for community building. (4) Building spirit, trust and interaction in the online environment relies heavily on technology in order to allow the students to interact via E-mail, a threaded discussion, web board or other communication technology. Students in the online environment may have been hindered by the technology or have been frustrated by the technology available at the community college, which might have contributed to a lower sense of spirit, trust, and interaction. Further research will be needed to explain fully the differences observed between the face-to-face and online groups. The null hypothesis that no significant difference existed between perception of learning and group was upheld. In other words, the students felt that learning occurred equally in the face-to-face and online settings. The finding supports the literature showing that classroom setting has no effect on student success (Hyatt, 1992; Nixon, 1992; Easterday, 1997; Russell, 1999; Wegner, Holloway & Garton, 1999). This is a positive finding for those who offer online classes.

Results of the univariate ANOVA indicated that the main effects of type (face-to-face or online), status (dropout or non-dropout) or type-status were not significant to the prescore. Sense of community was measured only once in the dropout group, at the very beginning of the course. Therefore, the null hypothesis that there will be no significant difference in sense of community between dropouts and non-dropouts was upheld. Consistent with the research (Phipps & Merisotis, 1999), the dropout rate was higher in the online group (12.6%) versus the face-to-face group (9.5%). Data on persistence must be gathered in order to establish reasons for the higher dropout rate in online courses in an effort to reverse the trend. Due to the limited sample size of dropouts, further research needs to be conducted in order to determine whether or not sense of community is compromised at the time the students drop out of a course.

Correlation analysis was undertaken to discern how the predictor variables varied in their inter-relationships between the two groups. Based upon the Pearson's product-moment correlation (Pearson's r) matrix, no significant relationship was found to exist between sense of community and age. This finding supports the research by Stokes (2001) who did not find age to be a predictor of student satisfaction of a digital learning environment. Although not investigated in this study, age has been found to be related to achievement and feelings of social distance with the instructor (Fiebert, 1971). Older and higher achieving students related better to instructors of similar age. Fiebert related this to the possibility that people of similar ages have more in common, find it easier to approach one another, and have a shared set of academic values. Fiebert also felt that older students might have a higher self-esteem, allowing them to overcome social distance barriers more easily.

Due to a non-normal distribution in course grades, Spearman's rho was utilized to analyze the relationship between sense of community and course grade (George & Mallery, 2001). No significant relationship was found to exist between sense of community and course grade. However, a slightly positive correlation was found between the sub-scale of interaction and course grade in the face-to-face group. This finding supports the literature suggesting that developing social ties from interaction is more difficult without face-to-face interaction (Flaherty, Pearce, & Rubin, 1998; Warkentin, Sayeed, & Hightower, 1997). McMillan and Chavis (1986) suggest that real learning does not take place until spirit, trust, and interaction occur. It is interesting to note that the group of students who scored highest on sense of community in the online environment was those students earning a grade of C, which may

BEST COPY AVAILABLE

support the McMillan and Chavis view that spirit, trust, and interaction have to take place before learning can occur. The online group scored lower on the four domains of spirit, trust, interaction, and learning.

Conclusions

The results of this study have important implications for urban community college educators as online courses continue to be developed and offered. Educators need to organize courses to ensure that the most effective type of interaction is taking place and that the interaction is suitable for the content area and students with different learning styles. The research suggests that instructors matter in the online setting and may have complete control over interaction and classroom dynamics (Arbaugh, 2000). Therefore, instructors need to learn skills necessary to promoting effective interaction. Perhaps large online classes will need to be divided into smaller groups in order to foster intimacy and trust among the students. The instructor might need to develop interesting, applicable discussion questions to aid the group in cultivating interacting skills. Study findings suggest that the face-to-face group of students experienced a higher sense of spirit, trust, and interaction than their online counterparts. If one agrees with the research that suggests that developing a sense of community will lead to a more positive course outcome and experience for those students enrolled (Dumont, 1996; Grossman, 1999; Rovai, 2001) then those instructors who teach online courses would benefit from building community in their online classroom. Instructor efforts, combined with pedagogical strategies that increase students' interactions may increase student satisfaction. Theoretically, curriculum-driven dropout rates might decrease, enrollments might increase, and satisfied students would be more likely to speak positively of their experience thus effectively promoting the online option within the institution. The positive experiences of students could translate into enhanced economic stability for the institution because those students who enjoy the educational experience may continue to pursue their education at the institution. Appropriate monitoring and evaluation of online courses by curriculum and assessment specialists would be imperative.

Classroom setting did not appear to have a significant effect on the subscale of learning. The face-to-face and online groups scored equally as high on the subscale of learning. This might suggest that pedagogical approaches could be more important at this time than the technology in determining the effectiveness of these courses. Those institutions utilizing technology to offer courses online need to be aware of such findings. However, use of technology plays an integral part in the online course and can have a beneficial or non-beneficial effect. The instructor needs to be familiar with the technology and be able to use course software to enhance, not detract, from the course. Technologies such as video, audio, and Web links can help to enhance the classroom experience by fostering more communication among students and between students and instructors. Communication based on these technologies might lead to an accelerated establishing of sense of community that previously was only based on textual input.

In this study, the online students who experienced the greatest sense of community earned a grade of C in the course. These students may have enjoyed the experience but earning a grade of C might preclude them from repeating the online experience. This could have both positive and negative implications for urban community college educators. If students do not continue to enroll in online courses a significant investment of resources are wasted. If students enroll in online courses, but are academically weak, faculty will need to be trained on how to optimize the learning experience. On the other hand, these "C" students, perhaps academically weak, sought out others for support and assistance, thus contributing to sense of community. Instructors of online courses need tools to help them evaluate the experiences the students may be having and how these relate to course outcome and students need to learn how to become effective consumers of educational experiences.

"Acquiring, Storing, and Sharing Research Datasets: Policies that Save Resources, Improve Collaboration and Research Activities using IT"

(This paper is currently a work-in-progress and will be completed by July 15, 2002)

Kemal Cakici
Multimedia, Networks, and Systems Specialist
Department of Management Science
The George Washington University
Washington, DC, USA

Jodi Felberg
Research Technology Coordinator
Center for Instructional Design & Development
The George Washington University
Washington, DC, USA

Abstract:

When university departments acquire, store, and share research datasets, IT support often finds itself struggling to reconcile several critical issues. Who pays for research datasets? Where are they stored? Who has access to them? How are they shared? How are they organized? What are the IT hardware and software requirements? Who supports the technology? Who makes dataset decisions, who provides funding, and who enforces the rules?

In this paper, we will examine the technical, financial, administrative, and political issues that surround research datasets and propose policies and procedures that aim to accomplish two important goals: (1) save limited resources such as money, storage space, and time, and (2) improve intradepartmental communication, academic research and dataset collaboration.

In an effort to address these issues, the Center for Instructional Design and Development at the George Washington University is actively involved in collaborating with, and forming permanent relationships with several Academic Departments, Information Systems and Services, Center for Academic Technologies, Gelman Library, and the Washington, DC area consortium libraries. This project was initiated in the summer of 2001 and we seek to have a strategic plan with milestones and major outcomes in place by July 2002.

We will present and discuss the challenges we faced, solutions we implemented, and our initial results from this project. We hope to outline the process in detail and explain how our experience can be used to enrich essential research activities, improve collaboration while decreasing the replication of research efforts, share the knowledgebase, and reduce the costs of data acquisition and storage at other universities.

Our presentation will be comprised of three parts: an examination of the problem and our proposed policy solutions; two case studies from our own experience that demonstrate how the dataset problems we encountered could have been minimized with the proposed policies; and an open discussion period where we invite feedback from participants and learn how other universities are dealing with this issue. Final paper will detail all these parts and relate their corresponding importance to a successful implementation of a collaborative knowledge management system in research activities of a higher education institute.

Proposed Policy Solutions: (work-in-progress)

(1) institute on-going meetings with IT specialists, academics, librarians, and administrators to open the lines of communication and dialogue in order to minimize political conflicts and power struggles;

(2) determine the number of replicated datasets as well as the critical datasets that are necessary for quality research but have not yet been purchased due to cost constraints or lack of information;

(3) setting ground rules and policies for ownership and funding of the datasets and access to these datasets

(4) determine the technical requirements and computer resources for instituting a centralized resource for datasets and research collaboration center

Other discussion points will include faculty perspective through interviews and brainstorming; computer software and hardware issues; managing and accessing library resources; setting the groundwork for collaboration with faculty and administrators through open communication and dialogue; networking and creating an effective working community among the IT department, academics, and administrators – the biggest challenge that all universities face.

Abstract: Intercampus is a pilot project of eight Catalan Universities whit the support of the Department of Universities, Research and Information Society of the Generalitat de Catalunya (Autonomous Government of Catalonia). Intercampus deals with the share of processes ranging from administration (Open Administration) to the teaching of subjects (Shared-Teaching between universities) through the net. Its objective is the exchange of free electives to be taught via the Internet. Students from a particular university, involved in the project, are able to study virtual subjects from any of the eight universities, it makes communication and information easier for these students and it coordinates service and administrative support between their own university and the university where the course is taught. The universities that take part in the project are: Universitat Autonòma de Barcelona, Universitat de Barcelona, Universitat de Girona, Universitat de Lleida, Universitat Oberta de Catalunya, Universitat Politècnica de Catalunya, Universitat Pompeu Fabra and Universitat Rovira i Virgili. Intercampus began in the second semester of the year 1999-2000. Up to now more than 1800 students from the universities involved have registered. There are 32 virtual subjects offered every year. The functioning of the project, the quantitative and qualitative results achieved throughout these five semesters as well as the evaluation carried out by the students that have taken part in the project will be presented. The information about Intercampus can be found in http://www.catcampus.org.

Introduction

The ICT are introducing changes in the current university model, they allow the fostering of new pedagogical methodologies and they make possible new ways of learning and communication between teacher and student and between students themselves. One of the applications derived from the use of the ICT in higher education is the possibility of distance teaching and learning through Internet.

Regarding the teaching/learning process, teaching through the Internet allows the student to solve the lack of time when learning the contents of the subjects and to take these subjects in a personalized way where and when it suits them best, as for their personal situation (time-space flexibility) and the immediacy in the access to the contents.

Intercampus is an example of how the use of the Information and Communication Technologies (ICT) in university teaching makes possible to share university processes ranging from administration (Open administration) to subject teaching (Shared-Teaching between universities) in a virtual way. The characteristics of this projects are developed below.

What is Intercampus?

BEST COPY AVAILABLE

It is a pilot experience consisting of the exchange of free electives (they allow students to take subjects which are not necessarily related to their studies) to be taught via the Internet. Intercampus allows students from any of the universities involved in the project to study virtual subjects from a specific university, it makes communication and information easier for these students and it coordinates service and administrative support between their own university and the university that gives the subject
Intercampus provides students new ways of information and learning: it allows the access to subjects which would be otherwise not available in their own university and it trains them in the acquisition of new abilities in communication and in the access to telematic information in a virtual teaching-learning environment.

The Teaching and Administrative areas of Intercampus

The main goal of Intercampus is to create academic and management mechanisms that allow the coordination between the universities involved in order to share and give access to their students to free electives via Internet.

In order to achieve these objectives, Intercampus has prepared two platforms interconnected to each other:

- Information platform: This free access platform informs about the general characteristics of Intercampus, its objectives, methodology and contents. It also has got information on the teaching that is offered (courses of each semester, their programs and specific requirements, the system of assessment, etc.). This platform is linked to the virtual-campus of the participating universities where distance teaching takes place.
  From this platform students can pre-enroll in the subjects and communicate with the Intercampus management. They can also have access to all the information concerning the adjudication of vacancies, the academic schedule and the evaluation of subjects.

- Management platform: This platform, which only the universities involved in the project can have access to, provides the academic and organizational support necessary for real time student management and for the evaluation systems to be carried out. The system has got the students' database that allows the elaboration of coordinated exams, the insertion of marks, the generation of the students' achievement records, and so on.

The Intercampus academic management is carried out by a general academic coordinator and the Intercampus academic coordinator from each university, with the collaboration of the respective academic management staff. Each university offers two subjects per semester, to be taught in their own virtual space. Intercampus acts as an infrastructure that gives support and allows the access to the universities' virtual spaces and coordinates the administrative and teaching aspects that are shared by the universities. Every year 32 subjects are given (16 per semester).

The following figures shows one screen shot of the general information platform, the 16 free electives offered through Intercampus in spring 2002-2003 are shown.

- Claus per entendre la Xina del segle XXI
- Com mirar una obra d'art
- Conflictes armats actuals
- Conèixer l'Islam, conèixer els musulmans. L'Islam: religió, cultura, societat i política
- Docència de les matemàtiques amb laboratoris virtuals
- Els inicis del comportament humà
- Empreses virtuals: estratègia i disseny
- English for Academic Purposes: Learning English through the Web
- Interacció d'humans amb ordinadors
- La creativitat: canvi i innovació
- Laboratori virtual de tecnologia
- Món global i economia
- Orientació professional a la recerca de feina
- Primers auxilis
- Temes actuals de marquèting
- Territori virtual a la societat de la informació

The offer ranges over several fields in education from humanities to technology or those related to learning of information and communication technologies, as well as foreign language (English).

Results

Intercampus began in the second semester of the year 1999-2000. Up to now more than 1800 students from the universities involved have registered. Intercampus offers 32 virtual subjects every year. We must highlight the fact that in every semestre the number of pre-enrollments always exceeds the offer of vacancies.

As for the participation of students, the number of preenrolled and enrolled students throughout these five semestres can be seen in the following table (table 1).

Table 1.Number of preenrolled and enrolled Intercampus students throughout the five semestres.

		Pre-enrolled	Enrolled
Year 1999-2000	**Semester 2**	645	264
Year 2000-2001	**Semester 1**	607	321
	Semester 2	952	369
Year 2001-2002	**Semester 1**	803	410
	Semester 2	1084	500
Total		**4091**	**1863**

The participation of students has increased throughout the years, which corroborates the success of the project. Regarding the evaluation of the project by the students enrolled in Intercampus subjects, every semester the project carries out a survey to these students in which they are asked to value from 1 to 5 they degree of agreeability in a series of questions related to academic aspects (programs, contents, materials, and so on), technical aspects (quality of the materials used through the net), virtual communication aspects (the supporting role of the teacher, how long it takes to answer virtual enquiries, forums, and so on) and general aspects (new learning and communication strategies as well as general satisfaction with the course) within Intercampus.

The reasults of the global evaluation are positive (most of the questions have got more than 3); in general, students are satisfied with their participation in Intercampus and they think that being involved in a project that provides them with strategies to study in a virtual learning environment is very positive. The detailed results will be presented in the announcement.

BEST COPY AVAILABLE

Conclusions

Intercampus – an example of the application of the ICT in university teaching- has overcome barriers that were immovable up to now, such as the stagnation of students in the contents and attendance requirements of their own universities. Perhaps the most important contribution made by Intercampus is the creation of an Open Administration shared by the universities involved in the project and the sharing of administrative processes as well as the contents (the subjects) that are taught through the net.

Intercampus is an innovative proposal which is closely linked to the offer and the needs of our society. This project fosters the use of new information technologies and shows how the Internet can be used to shorten distances, both academic and administrative, between universities.
The positive evaluation by the students and universities involved in Intercampus make possible the way to the consolidation of the project, so that it becomes part of the normalized offer of the free choice subjects given by the universities involved.
A new path is open. The university overcomes time and space barriers as well as those barriers related to the processes of administration and to the contents given. There are new possibilities of collaborating between universities.

Intercampus is supported by the Department of Universities, Research and Information Society of the Generalitat de Catalunya (Autonomous Government of Catalonia)

WEB PORTALS: A DIFFERENT VIEW FOR FACULTY DEVELOPMENT

Patricia A. Carlson
Department of Humanities and Social Sciences
Rose-Hulman Institute of Technology
United States
Patricia.Carlson@rose-hulman.edu

Abstract: Accomplishing change in education starts where learning begins: with the classroom teacher. Rose-Hulman Institute of Technology (with support from the Lilly Endowment) is constructing a Web portal dedicated to improving middle school science, mathematics, and technology (SMT) instruction. Essentially, this gateway emulates emerging corporate practices of knowledge management and process re-invention through information technology (IT). We expand the notion of "professional development" to include not only training in computer competency (explicit knowledge) but also mentoring in the higher-order understanding (tacit knowledge) necessary for meaningful integration of instructional technologies into the classroom. Our portal creates a "community of practice" for middle school teachers across Indiana to share experiences and to harvest the remarkable opportunities for improved SMT learning through Web-delivered simulations, visualization, modeling, access to live data, *and* to enable new collaborations, interactive learning, and alternative pedagogical approaches. Rose-Hulman faculty and digital media specialists serve as partners by providing ongoing advice, hosting special Web-conferences, and helping to author classroom modules.

Connecting with the Future

Our goal is to improve learning in middle school SMT by helping to improve teaching. Certainly, we are not unique in declaring such a goal. We realize that national concern in the past decade alone has created significant opportunities for improvement in SMT instruction. For example, the reform guidelines given in the National Science Education Standards (1996) call for more inquiry-based classroom activities and more effective use of instructional technology. Additionally, Web-delivered instructional media -- many developed through substantial investment from NSF or NASA -- now abound. These digital resources have the potential to redefine the traditional roles of student, teacher, and classroom in the near future. But harvesting this potential requires that classroom teachers have more than just entry-level proficiency with basic categories of instructional software. Teachers must be both encouraged and supported in coming to understand computers as powerful devices for expanding their own dynamic presence in the classroom.

The Knowledge Gap

Examining the challenges for workforce modernization in education, we isolated two critical hurdles that must be surmounted in order to improve middle school SMT instruction.

- The ever-widening gap between the production of quality, Web-delivered instructional new media and most middle school teachers' ability to meaningful integrate these advancements into their curriculum and their classroom activities; and
- The demands placed on teachers by new reform guidelines -- both state and national -- that call for less dependence on textbooks, lectures, and de-contextualized lab work and more emphasis on inquiry-based learning containing real-world contexts that combine science and mathematics "to solve a human problem, met a societal need, or develop a product" (National Research Council, 1996, p. 161).

Focusing on these two needs in planning our portal, we started by taking a look at how information technology (IT) addresses the perennial issue of professional renewal in an academic context. In defining the challenges for professional development in education, we went beyond baseline competency in instructional technology and worked toward a more comprehensive view. We used emerging concepts in *knowledge management* (KM) as a framework for defining "professional development." In our high-level design, we paid specific attention to the distinction between *explicit* knowledge and *tacit* knowledge (Ryle, 1984; Reber, 1995). This distinction between types of cognitive growth (i.e., knowing *that* and knowing *how*) appears widely in discussions of student learning but seems to be less prevalent in planning for an instructor's continuing education.

A cogent explanation of the differences between explicit and tacit knowledge in an organizational context is given in Kidwell, Vander Linde, and Johnson (2000). Explicit knowledge is easily codified and can be embedded in readily transferable artifacts, such as rules, procedures, policy statements, databases, books, and other forms of concrete representation. Tacit knowledge, on the other hand, is less definable, less manageable, and more fragile. Typically, it resides in human minds in the form of insights, complex decision-making abilities, judgment, situational awareness, and know-how drawn from experience. Because it is not easily formalized, tacit knowledge is difficult to transfer using the traditional training channels currently available (p. 29).

Applying this framework to education, we concluded that teachers (at any level) can be overwhelmed by the sheer amount of instructional applications coming both from commercial and from research-funding developers. Thus, we structured our portal to address our specific concerns about the *ever-widening gap* between top-down, systemic opportunities/changes and the individual teacher's ability to incorporate these new ideas or items into a coherent plan that can be enacted in his or her classroom on a daily basis. In short, we address the classic organizational problem of a *knowledge gap*: what to do when new methods of operating advance more rapidly than members of the organization can meaningfully assimilate and implement.

A Community of Practice

While the technology for all portals is basically the same, their underlying philosophy and purpose vary. The portal we are building -- tentatively called **SMART** (**S**cience and **M**athematics **A**ccess to **R**esources for **T**eachers) -- creates a community of practice for a large, geographically dispersed group of educators who now have only a few state-wide forums and perhaps even fewer opportunities to forge working relationships with kindred spirits. Models for this type of "virtual community" are abundant, and reliable studies of their efficacy indicate that the approach has merit. Additionally, well-thought-out computer supported collaborative work environments (CSCW) that nurture group collegiality and facilitate sharing of talents have a relatively long history of success in the corporate workplace

Our Web portal aims to capture some of this power in order to achieve four specific objectives.

- **Reinforcing Collaboration and Collegiality:** Teachers from one end of Indiana to the other can share ideas, collaborate on projects, disseminate best practices, and network expertise. This "community of practice" aspect of the portal promotes the sharing of tacit knowledge and provides the virtual context that sustains professional renewal on a daily basis and motivates the use of advanced technology in the classroom.

- **Reducing Disparities between School Districts:** Although state educational systems work hard to maintain standards and to ensure equity, certain variables (for example size, socio-economic profile, rural or high-risk urban environment, and local demographics) create disparities that make it more difficult for some schools to achieve the quality of instruction all citizens of Indiana should have. As an enabler, our Web-portal delivers access and opportunity to all. Additionally, its "virtual environment" works to marginalize some of the constraints imposed by the physical world.

- **Providing Expert __Human__ Intervention**: Just as large, complex, traditional libraries are best used in conjunction with a trained reference librarian or special collections librarian, so too are the vast information spaces of the Web best explored with the help of an expert guide. Our digital librarian will set up a clearinghouse for existing materials. More importantly, s/he will be available (initially via email and later using video conferencing) to offer "real-time" advice and guidance. Designated Rose-Hulman faculty/partners will also help to mentor and facilitate in a variety of ways.

- **Facilitating Professional Development:** A variety of training modules – featuring new pedagogy, curriculum design, and classroom innovations as well as teaching various aspects of computer/advanced educational technology competency – accommodate all levels of ability, from novice to advanced learner. Also, online workshops will be developed by Rose-Hulman faculty showing how to integrate engineering and design projects into the middle school. Availability and ease-of-use encourage the continuous reinvestment in human talent necessary for quality teaching.

Portal Features

SMART is conceptualized as a highly interactive, highly mediated gateway where Indiana middle school SMT teachers can browse timely content, download instructional software, and retain a customized account that will automatically alert them to items of interest (as determined by their user profile). Additionally, teachers can submit materials for posting, can host their own "homepage" on the portal's server, as well as enter into synchronous and asynchronous discussions on topics of interest, and can take part in vital professional development/in-service training through distance education capabilities. We emphasize that SMART is a well-designed workspace (emulating an integrated desktop) that seamlessly combines the four types of learning and management tools delineated by Eisler (2001, p. 6):

1. A *gateway* that helps to manage the overabundance and discontinuity of information on the Internet.
2. *Points of access* for "internal information" (databases of lessons/activities and best practices submitting by individual teachers or participating professional groups), configurable for constituent groups (e.g. grade level, subject matter, special interests, geographic area, and the like).
3. *Communication channels* facilitating various types of information flow (e.g. "pushed" information such as time-critical announcements and "pulled" information such as bulletin boards and online special events or public forums).
4. *Communities of practice* and *learning hubs* (e.g. tools for collaboration – beyond the traditional file transfer and chat room capabilities -- including interactive, collaborative learning support systems).

Faculty Development and Process Re-invention

Organizational researchers such as Tom Davenport (1993), Michael Hammer (1996), and Peter Senge (1990) stress fundamental workplace change through re-invention or reengineering. Though their exact terminology differs, the commonality for all the "new paradigm" thinkers hinges on the transition from an industrial model to an information model.

Basically, core business practices in the former are viewed as an assembly line, with tasks being partitioned into small segments and passed from worker to worker. Heavy emphasis is placed on explicit knowledge (procedures) and very little on tacit knowledge (individual variations). In contrast, work in an information age is seen from a process orientation. The consequences of this new model are dramatic. Workflow is no longer strictly linear. Workers are encouraged to take on more responsibility in self-managing their tasks. Ideally, within the modern workplace, employees should feel more confident and grow in self-esteem. Emphasis is on creative problem solving, mindful engagement in the task, and greater participation in decision-making. In short, a larger commitment is now made to developing tacit knowledge in the workforce, and collaboration has become a major enabler for nurturing and transferring wisdom in an organization. Within this context, the enterprise information portal holds great promise for establishing strategic alliances, mentoring employees at all levels, and exchanging experience and information (Collins, 2001).

"Reinventing" has mandated a fundamental change in the meaning of "professional development." That much of the U. S. workforce is making a profound transition from employee to knowledge worker is widely acknowledged. Peter Senge's *The Fifth Discipline* (1990) describes private sector organizations that have become "learning companies" through a continuous reinvestment in their human resources because the worker in the 21st century will need to be flexible, tolerant, and highly adaptive. Like business and industry, dramatic changes in education appear to be "re-inventing" the process of teaching. In all likelihood, tomorrow's teachers will enact a pedagogy that is open-ended and requires complex problem solving using "best judgment" to navigate through choices. While explicit knowledge (subject matter, task procedures, and classroom practice) will still be foundational to teaching, tacit knowledge (creativity, reflective judgment, and context awareness) will become the *sine qua non* for excellence in teaching.

To facilitate the type of ongoing professional development needed in education today, we have looked to the corporate world, where rapid change necessitates computer-enabled models for workforce enhancement. The appropriateness of making comparisons between business and education may be debatable; however, both enterprises do face the same challenge of needing to re-invest heavily in their human talent in a time of rapid change. In fact, finding ways to sustain the constant renewal of competencies necessary for the modern-day knowledge workers has occupied the private sector for some time now.

Interestingly, corporate America has had to relearn some fundamental principles about the value of individual insight and initiative as well as the need to reward commitment and to foster collaboration. In the search for methods of renewal, information technologies that enable and empower have been instrumental in re-inventing the process by which many companies and corporations accomplish their mission (Davenport, 1993). At the forefront are networking applications because they (1) keep a constant flow of knowledge moving through the enterprise (2) make possible a "community of practice" among individuals and groups no matter what geographic or organizational boundaries separate them. For models of *process re-invention*, education might well borrow some of the lessons learned by private enterprise in the last decade.

Acknowledgment

We express gratitude to the Lilly Endowment for its generous grant to fund the project described in this article.

Veterinary Multimedia Repository: An Example of a Web-Based Collaborative Tool for Organizing, Archiving and Retrieving Pedagogical Chunks.

Project Background

The dual mandate of clinical teaching and research activities at the Faculté de médecine vétérinaire of Montreal University (FMV) is being traduced by a huge production of original multimedia content. With time, faculties and searchers at the FMV accumulated a significant amount of analogical multimedia documents: 30 to 40,000 slides (with 16,000 slides in pathology alone), hundreds of surgery video clips (small animal or large animal clinics, ambulatory clinics) and clinical procedures (anesthesiology, gait exams, neurologic exams), dozens of echography, more than 40,000 x-ray films and thousands of medical files. The digital shift started a few years ago in the clinical activities and technological integration has cause an augmentation of digital multimedia material to be spread on many different FMV computers.

It rapidly became a priority, primarily, to digitize all of these analogical documents for preservation and availability purposes; and secondly, to integrate all of the different aspects of digital information management (production, treatment, archiving and distribution) in a one-stop location that is widely available for everyone to meet all of the end user needs. The Laboratoire d'intégration des technologies informatiques en enseignement médical or laboratory for information technologies integration in medical teaching (LITIEM) has established a data repository project with those specifics aims:

1. Achieving actual analogical material scanning (slides, audio-visual documents, medical imaging and papers),
2. Archiving material via on-line databases (data entry and inquiry), and
3. Organizing the material to maximize its potential utilization.

Content Organization

Content Organization is a prerequisite for an effective inquiry in any database. That's why it is an essential aspect of this project. A digital database effectively designed is no longer a simple data archiving system as it has become a powerful training tool. A database of this kind may be used; as an example, for fast creation of a clinical demo case on disease affecting a particular system (respiratory, digestive, etc.), for a specific species (dog, cow, etc.) and in the context of a precise specialty (internal medicine, surgery, hematology, medical imaging, etc.) or to create virtual clinical rounds.

The main challenge was to develop a series of protocols and tools intended to limit the direct interventions of the faculties and the technical staff in the data entry, the treatment, the archiving and the distribution of the multimedia material. It was also necessary to decentralize the points of access of the information because the clinical activities take place in remote physical places. We have questioned the strategies of management on the information necessary for the optimization and the automation of the processes required between the production and the broadcasting of the digital material. To facilitate the appropriation of the digital technologies by the unexperienced users, the LITIEM created a vast accessible media library via dynamic web pages in ASP language and the engine that is a SQL database. The simple interface allows the content specialist to organize and to index the multimedia contents produced by its clinical and teaching activities without possessing knowledge in programming or in web pages construction. The media library is a flexible platform that allows to bind together the contents that are similar in an unlimited number of distinct libraries to satisfy the needs and criteria of the classification appropriate for the various veterinary fields (ex: companion animals, farm animals, pathology, bacteriology, etc.). Conversely, a unique and common research interface to the various libraries assures the end user to locate all the relevant documents they require without having to question the libraries where to make the search.

Collaborative Workflow

Scanning analogical materials

The scanning of analogic material for the project is under request by specific faculty members and is accomplished by student or clerical staff with equipment provided by the LITIEM. Simplifying and automating procedures has been the goal of the project team to minimize training time and the error rate. Each slide scan creates 1024 x 1500 pixels 600 DPI 32-bit color JPEG images. After this process, images are treated as digital documents.

Data Entry Module

To archive the new material in the media library, a faculty member or his deputy has to first of all download the digital files in a secured virtual directory without caring about characteristics of the file (name, size, file format, etc.). Once the documents are gathered on the central server, the clerical staff is capable of creating an index file for every multimedia document produced. This descriptive index file is unique in the database and it always accompanies a document archived in the media library. This index file contains all the descriptive fields such as the specie, race, age or the diagnosis of which are essential to retrieving and locating documents. To avoid disturbing the contents specialist in this early stage, the only necessary keys to create an index file is basic information that can be identified by a non-specialist: the specie (dog, cow, etc.), the implied system (respiratory, digestive, etc.) and the type of media (photos, videos, 3D animations, sounds, etc.). It's possible to include several documents of the same nature in a series to illustrate the various stages of the same procedure or the various states of the same disease. When the index file is created, it passes in transit towards the audiovisual technician responsible for the digital treatment of the multimedia documents.

Technical Module

This module allows various specialized technicians (images, sounds or videos) to download every document archived in the database directly to their workstation for treating and optimizing the data. In the case of the images, cropping, filtering or certain adjustments are often necessary. For the audiovisual documents, some editing or effects can be required. At first, the technician manipulates the raw data of the document without precise directions. It is possible that a faculty member will return a document with a demand of precise modifications via one comment field of the index file, which may be only viewable by the owner of the documents and the technician. In the case of the images, it is at this time that the technician re-samples the images to create the four (4) sizes used in the media library: 1024 x 1500 pixels with 600 DPI of resolution for the printing, 640 x 480 pixels maximum with 96 DPI of resolution for the electronic presentations (PowerPoint for example), 320 x 240 pixels with 96 DPI of resolution for the web applications and 100 x 100 pixels with 96 DPI of resolution for thumbnails used in the search interface. As soon as the treatment of the document is completed, the index file is returned to the faculty owner for final approval.

Validation Module

When the faculty member is ready to validate the multimedia documents, he simply has to connect the database via an Internet browser. The access is personalized and secured with a log-in and a password. Once identified, the faculty member can easily observe the list of the documents that belong to him and which are waiting for his validation. He simply selects the unique document or a series of documents and can then begin his work of validation. He verifies, first of all, that the document is relevant and if he considers it necessary, he can simply delete it. He then has to verify the technical quality of the document and if need be, he can re-direct the document to the audiovisual technician for specific treatments. Finally, he completes the index file with the clinical data associated to the multimedia document. It takes less than two (2) minutes to complete an index file because it is constituted by interdependent rollover menus. For example, a list of the diagnosis is directly connected with the selected system and with the chosen specie. As soon as the owner is satisfied with the contents of the index file, he can validate it and it becomes then available for the consultation. All the power of this module lies in its ample flexibility at the collaborative level. Indeed, a faculty member may decide to ask for a second opinion of another specialist, he can delegate the validation to a student or to another specialist, he can include documents in a series or extract a document of a series and he can also modify or complete an index file at any time.

Consultation and Visualization Module

Although documents are archived and classified in different libraries, it's always possible to make a single search that crosses among all the libraries. There are three (3) levels of consultation: open to the public for the images accessible without limitations, Intranet for the images intended for internal usage and private viewing for the images that belong to one particular person. To be able to see the Intranets and privates images, it's necessary to log-in with a password. The results of the search are presented as thumbnails and they are grouped together by document types (images, videos, etc.). When a user clicks on a thumbnail, it shows a web format image with its descriptive index file. It's then possible to save the image for later use. The high-resolution formats are only accessible via the Intranet to avoid the non-compliance red tape with copyrights.

Future Directions

Teaching in a medical context benefits two fold from an integration of information technologies in the learning strategies because of the highly multimedia character of the various topics (videos, photos, illustrations, sounds, medical imaging, etc.), of the existence of numerous abstract patho-physiological concepts and the necessity of creating simulators intended to enhance problems solving by learners. For all these reasons, sharing resources between faculties favours the realization of didactic quality material. It's easier to coordinate the available documents via a unique source and so promote the creation of original material while avoiding to the faculties the recreation of already existing material. The continuation of the project consists by connecting the media library to a direct link with our applications of off-site learning and our clinical case simulators by decreasing the time of creation for the pedagogical tools by the content specialists.

Abstract

The Changing Technology in Management Project, at Sheffield Hallam University in the UK, has been investigating the issues surrounding the integration of technology into teaching and learning. This is a preliminary report which identifies the limitations of prescriptive methodologies, such as the North American Teaching, Learning and Technology Roundtables, in three diverse institutions in England. The authors posit that cultural sensitivity to the organisation is the vital base upon which to build meaningful and enduring technological change.

Introduction

There is a general consensus that change is an ever present dynamic and, according to some, this has been particularly resonant in higher education (*cf.* Halsey, 1995). The shift from elite to mass higher education (HE) has forced English institutions to re-evaluate their provision. This has been distilled into a single policy question: How can institutions deliver a high quality product, to a greater population, with diminishing resources? Since the mid-1990s critiques began to appear which heralded the potential of information and communication technologies (ICT) as a solution to these concerns (*cf.* Ehrmann, 1996). As we are becoming conversant with the integration of ICT into teaching and learning, we have found that both the underlying trends of change in HE and in ICT have combined to shape the way we manage technology. These can be summarised in the following key areas:

- macropolitico-economic change and, specifically, the transition towards a knowledge economy. The Council of the European Union (2001) described a vision whereby Europe becomes "the most competitive and dynamic knowledge-based economy in the world capable of sustainable economic growth with more and better jobs and greater social cohesion" (p. 2);
- the changing face of accountability, where institutions are increasingly tightly controlled by governmental agencies (such as the Quality Assurance Agency in England) and the increasing demands of students as consumers heightened by the recent introduction of the undergraduate tuition fees;
- the nature of technological developments mean that change is uncertain and unquantifiable: because one cannot predict the form of the challenges that lie ahead, in a real sense, it is difficult to manage strategically; and, incongruously,
- as funding has generally fallen in the sector more has been spent by institutions on technology in the hope of reducing long term costs (reducing tutor-student contact hours) and also generating income through the commercial possibilities of e-learning.

The Changing Technological Management Project

The Changing Technological Management Project was established to investigate how technological management in education can be made more effective. This study was an eighteen month project which began in September 2000

funded by the Joint Information Systems Committee (JISC). The original focus was to trial the North American Teaching Learning and Technology Roundtable (TLTR) methodology. However we quickly learnt that there were wider issues to be considered, particularly those relating to institutional culture, which will be detailed during the course of this paper.

For many in higher and further education, the experience of integrating technological innovation with teaching and learning has been haphazard and uncoordinated. Even where specific groups or individuals have been established to manage this process, there have been charges that they have focused narrowly on either the 'technology' or the 'teaching' and 'learning'. As a result, TLTRs were developed by the TLT Group (an affiliate of the American Association for Higher Education) as a methodology for integrating teaching and learning with technology. Roundtables have been defined as "a diverse group representing those who can and should work together to improve teaching and learning with information and communication technologies" (TLT Group, 2000).

Specifically, within the context of English higher education, the project was charged with three main aims:

- to discover how roundtables are used;
- to investigate their effectiveness and value, and
- to identify strategies for the successful management of technological change.

Overview of the Research Methodology

The investigation was primarily qualitative in nature and the specific features of the research methodology were as follows:

- case studies in three principal sites: an 'old' research led university (Institution A); a former polytechnic (Institution B); and a community FE college (Institution C). The key methods employed were structured observation and interviews;
- informal visits to other UK institutions;
- semi-structured surveys of UK experiences (followed up by a series of telephone interviews); and
- face-to-face and telephone interviews with North American institutions who have experience of TLTRs.

It should be stressed that the investigation is still continuing but very illuminating data has already been elicited. The remainder of this paper reports these findings.

Experiences in the Institutions

As one would expect, a very different culture and management system was in place at each institution. This can be explained by their vastly different traditions. Institution A could be characterised as a conservative, collegial university with a high research income and somewhat traditional values. Institution B has more modest income from research and is heavily reliant on student tuition fees as a source of income. It is assumed to be more managerial than its older counterpart and perceives itself to be more dynamic. Institution C, on the other hand, is operating within much tighter financial constraints than its university counterparts. It is highly managerial as evidenced by, for example, the existence of a "Chief Executive Officer" rather than a Principal. All three institutions enjoy close ties owing to their geographical proximity to each other. While a second common denominator for all the institutions was that each was interested in the development of some form of e-learning.

The first task of the project was the identification and recruitment of dedicated champions who would be charged with the responsibility of promoting and implementing the TLTR methodology in their respective institutions. The TLTR methodology encompasses a series of prescribed activities in sub groups (Gilbert, 2000) that seek to establish:

- clear objectives and agreed goals *vis-à-vis* technological management;
- develop a climate of openness;
- develop appropriate leadership; and
- reviewing team processes.

At this stage there were three immediate issues, namely: the influence that the champions could bring to bear on the institution; the appropriateness of the methodology itself; and time needed to establish the roundtables. First, if the champions were to have any chance of establishing the groups they needed to fulfil a number of criteria, which are to be found in other lessons from change management (Goulding *et al.*, 1999). As the *de facto* leaders of the group they needed to have enough seniority to be able to inspire commitment from senior management whilst also being a 'respected insider' to gain the confidence of teaching staff. Additionally we found that they needed to be imbued with enough political acumen to know how to use their influence to keep the roundtable vibrant. Our experiences are in keeping with Baldridge *et al*'s (2000) depiction of the "strategic ambassador" approach to leadership, which places the leader at the centre of concentric social circles rather than the peak of the organisational pyramid.

As far as the appropriateness of the methodology was concerned, more fundamental problems arose when the prescribed tasks were first introduced to the roundtables. At two of the three institutions the membership treated the tasks as being entirely inappropriate. Only Institution A considered the use of the workbook but even here it was at a much lower level (i.e. in a sub-group with minimal influence on institutional strategy) than had originally been envisaged. We have found that all the institutions' receptivity to the methodology was inhibited by two key factors: the prescriptive thrust of the workbook was alien to the organisational cultures of the institutions investigated; and the workbook was not sufficiently sophisticated for roundtable members to feel they would benefit (deriving from their assertions that similar thinking had already been completed). This assumption was corroborated by survey data and informal visits by the researchers to other institutions. In conclusion, the prescriptive thrust and lack of sophistication conspired to condemn the methodology to be viewed as just another 'bolt on' programme that would be peripheral to the institutional culture and soon forgotten.

It was noted that all the roundtables needed considerable time to establish themselves and be subsequently incorporated into the institutional decision-making process. There was a correlation between institutional type and the speed of establishment. Institution C, the most managerial institution, established their roundtables within weeks: Institution A, the 'old' research-led university, established theirs after many months' negotiation. In general, our experiences substantiate the conclusions reached by a US study which verified that the lead up time in American institutions was between twelve and eighteen months (Nardick, 2000).

Interestingly respondents at all the institutions distinguished between 'roundtables as an approach' as opposed to 'the roundtable methodology'. While the latter has connotations of directiveness, the former was recognised by many an opportunity to articulate aspirations of collegiality. The drive of managerialism in England (Deem, 1998) has all but eradicated any meaningful collegial systems (Ramsden, 1999). The 'roundtable approach' which has elements of dispersed leadership, representatives from the campus community and ownership over decision-making, appears to map well onto the sense of community that is embodied in highly valued concepts of collegiality. It may well be a reaction against the endless tide of managerialism, which makes this allusion to legitimacy all the more persuasive and seductive. At Institution C we found that while the development of policy was more time consuming, as one may expect from such a democratic model, the consideration of multiple viewpoints has led to a perception that policy making is more robust than it had been previously. Whether this is a correct interpretation, or replicated in the universities, will be uncovered by future research.

Conclusion: Points for Discussion

We present a set of discussion points rather than concrete conclusions. This is based on our stated depiction of the project as one in progress. Three pertinent questions, which we feel may be applicable to the management of technology in any organisation, emerge from our experiences:

- can methodologies developed for one education system ever be transferred to another?
- can prescriptive methods secure palatable and enduring change? and, having identified these two questions,
- where does one start the process of change?

It is evident that a constant theme in our investigation is one of 'ideology'; the ideological underpinnings of the culture of the institution and of the methodology. While technology creates a stimulus for accelerating change we need to be ever more sensitive to the cultures of the organisation.

SUPPORTING THE DEVELOPMENT OF STUDENTS' VIRTUAL ENTERPRISES: AN E-LEARNING ENVIRONMENT

Alessandro D'Atri, Francesco Barbini, Nunzio Casalino, Oleg Missikoff

CERSI - Centro di Ricerca sui Sistemi Informativi
Luiss Guido Carli University – Roma – Italy

Abstract: This paper describes a research in progress, aiming to develop and evaluate an innovative on-line training support system for students attending the Young Enterprise Europe (YEE) "learning-by-doing" formative method. The main goal of the research is to develop, starting from the results of the FAIRWIS research project, described in the paper, a new environment enabling student-managed laboratory enterprises to efficiently set-up and exploit inter-organizational cooperation, while assisted by an on-the-job training/learning support system. The paper presents the ongoing research activities and depicts foreseen evolutions. In particular, it is proposed to apply an innovative training system able to enhance present training methods adopted by YEE. This system would also allow YEE students to improve their managerial skills and let laboratory enterprises work in a more realistic, yet simulated, environment.

1. Introduction

This paper describes the use of a web environment implemented for managing real and virtual trade fairs as an educational tool for helping "laboratory enterprises" of students from European High Schools and Universities to follow the educational method proposed by the no-profit association Young Enterprise Europe (YEE, see web site at www.young-enterprise-europe.com).

The validity of this environment as an educational tool has emerged during the FAIRWIS (IST-1999-12641 Trade Fair Web-based Information Services) EU-funded project thanks to the tight cooperation between the IGstudents Foundation (the Italian branch of YEE) and the Centre of Research on Information Systems (CeRSI) of Luiss Guido Carli University in Rome (D'Atri 2002b).

The main goal of FAIRWIS was indeed to develop technological services for simplifying contacts among companies during trade fairs, and therefore looked ideal as a support system for students micro enterprises following the IGstudents training process (D'Atri 2001) (Pauselli 2001). This enterprises network was one of the pilot validation contexts for the system prototype.

The next section is devoted to a thorough analysis of the IGstudents training programme. Section 3 will sketch the foreseeable developments of FAIRWIS. The application of FAIRWIS system to support inter-organizational cooperation among laboratory virtual enterprises is described on Section 4, while the Section 5 will analyze the educational support necessary this innovative environment. A discussion will follow.

2. Young Enterprise Europe Training Programme

The motto *"Studying for job creation, not for job searching"*, introduces the method developed by YEE (Young Enterprise Europe), and applied in Italy by IGstudents, based on the learning-by-doing approach.

The aim of the YEE Programme is in fact to create a bridge between the worlds of education and employment, develop entrepreneurship capabilities and produce the cultural and professional premises to ensure that young people achieve a sense of independence and alternative means of employment.

The exemplarity resides in the innovative aspects of the proposed educational system that represents, in fact, the first such experience realized in Europe, for what concerns both the number of students involved and the formative plan, in terms of contents, modality and training method.

The system, co-ordinated in Italy by the IGstudents Foundation, is at its third year of realization and it is integral part of the YEE international circuit gathering 19 European and Mediterranean organizations that carry on in the respective countries the formative program. The validity of the methodological formulation is guaranteed by the fact that such program has been used since the years '60 in England, and has progressively spread to other countries achieving the involvement of around 600 thousand students every year.

The general objectives for the users of this system are:

- Acquire awareness of his/her own personal abilities and professional potential for the future working life;
- Develop enterprise culture;
- Study and experiment a European education model;
- Create and manage laboratory micro enterprises with financial resources;
- Acquire and develop transversal competences: from the ability to work in groups to communication, to work for objectives, to decision making and solving of complex organization problems, to the management of emotions;
- Create skills by means of an integrated system of actions, from orientation to training and stages, from tutoring to accompanying measures, from the laboratory to the market;
- Acquire the culture of "working and living with equal opportunities", valorising the potential of diversities and preventing phenomena of isolation and disparity;
- Exchange experiences at local, national and international level.

Trade fairs have a special relevance in the IGstudents training programme as they are the moment of confrontation for students having worked on their enterprise throughout the academic year. During those events students have a chance of seeing real enterprises managing their own business, and are stimulated to make constructive comparisons between the way they have carried out their business idea and the way this activity is managed by organizations working in the open market.

3. Virtual Vs. Traditional Trade Fairs

Trade fair events, in fact, play a central role both in the commercial and in the industrial business because all participants to such events, both visitors and exhibitors, have access to great opportunities for expanding their activity.

Relevant characteristics of these events are:

- they are limited in time (one or few days) and usually periodically scheduled (every week, month or year);
- fairs are usually oriented to a particular market sector (e.g., agriculture, information technology, tourism) or specialized in a thematic field (e.g., wedding, cartoons, Xmas presents).

BEST COPY AVAILABLE

Even if trade fair activities often include selling products, more important goals for the participants are:

- exhibit and advertise new products' features;
- train professional operators;
- reduce the distance between enterprises and customers.

In fact, people attending fairs can access knowledge about emerging markets, innovative products and services. Furthermore, a trade fair event can be considered as an important opportunity to meet and aggregate people having similar interests and to establish business contacts among partners, concurrent enterprises, customers, suppliers and professional workers, as it happens in other kinds of events as conferences or workshops. Due to this similarity, some large conferences have industrial exhibitions which run in parallel and, often, a "meeting program", based on workshops or seminars, is included in a trade fair agenda.

The above described benefits are particularly important for micro and small enterprises and even more for students enterprises. In fact, it is not easy for small enterprises to have direct contacts with other companies in their field, especially those in larger (European or international) markets. The main problems are:

- poor financial resources;
- limited knowledge of foreign markets;
- different languages and cultures.

However, for obtaining these advantages, the organizations have to devote a large share of their resources to fair activities and, obviously, the smaller is the enterprise the greater are the difficulties for participating to these events. When these organizations are exhibitors, they have to face high costs (e.g. to rent an exhibition area, design and set up the stand, transport goods, pay exhibition staff, and so on). When they participate as visitors, and the trade fair location is far, they have similar (travel and accommodation) cost problems, together with a strong reduction of normal daily activities, before, during, and after the event. For these reasons micro and small enterprises participation to these events is often restricted to the (minor) ones held in their geographical area.

Only recently it has become possible to find specialized web sites that support trade fairs events. These sites offer new kinds of services (though still limited in number) oriented to trade fairs organizers, exhibitors, and visitors. Until now they are unfortunately not organized in a homogeneous or comprehensive way, and are usually presented in a rigid pre-designed company oriented way.

For that reason a new Internet based e-commerce solution for trade fairs has been the subject of the FAIRWIS project, carried out by a heterogeneous group of organizations (software companies, universities, research centres, and fair organizers).

4. FAIRWIS Evolution

The "laboratory enterprises" participate to a competition and so, after having gone through a mechanism of progressive selection, the most interesting and well implemented projects end up taking part to regional, national and international trade fairs. The possibility provided by virtual, web based, trade fairs management systems such as FAIRWIS, allows a relevant increase in the number of enterprises participating to such events (Muscogiuri 2002).

The analysis of the training programme applied by the YEE/IGstudents, has stimulated a proposal for an enhancement that could widen up the perspectives of the educational method. In fact the laboratory enterprises are developed not only independently but, moreover, in competition among them for climbing up the ranking ladder and possibly winning the final contest. This makes it impossible, or even counter productive, any contact between enterprises until they start the final stage of the learning process when the best performers go to regional and national finals.

On the other hand, the contemporary real market, competitive, complex and dynamic, is forcing enterprises to overcome traditional economics of scale, emphasizing instead the competitive importance of specialized competencies and inter-organizational cooperation. Dynamic networks of Small and Medium Enterprises (SMEs) are becoming the most promising model both in terms of technical possibility to link autonomous information systems and in terms of benefits (Ba 1999).

Thanks to the progress of tools and technologies seen in the recent past, it is now possible to achieve a concrete integration between different organizations (Nayak 2001). The prerequisites for the implementation of this model lie in the achievement of a thorough integration in terms of both information systems and business processes (Rockart 1991) (Wigand 1999).

This model, often referred to as "virtual enterprise", is more complex than the traditional one. Although the most recent information technologies can provide useful supports for allowing interoperability, there are still mental resistances that make the transition to this new model slow and difficult.

In this perspective, the introduction of this new element in FAIRWIS (Barbini 2001) and, in the near future, in its educational model could be of great help for forming more open minded future SMEs managers, ready to apply state-of-art organizational methods.

5. Towards a Laboratory Virtual Enterprise

The evolution of FAIRWIS will rely on the virtual organization paradigm mainly because of two reasons:

1) It is the emerging organization model in the new, complex and competitive market. It will foster youths to acquire a state-of-art entrepreneurship skill.
2) It is particularly suitable for learning/training and to manage knowledge in a wide, social context. This because the virtual organization is a learning context: at any given moment can be considered as a collection of skills, talents, and experiences that reside in the minds of its managers and workers, and a body of information relating to its products, its internal structure, and its business relationships.

Even though we are experiencing strong enhancements in business-to-business, business-to-resource and business-to-customer on-line interaction possibilities, none of the proposed solutions seems to be suitable for developing, organizing, and integrating, i.e., "incubating" virtual enterprise organizations. Indeed, virtual enterprise organizations may flourish only if appropriate humus is established, by providing added value services enabling to overcome the inhibitor factors. However, this can only be achieved if a sufficient degree of scientific insight, education, and practical experience with respect to the concepts and methodologies of virtual enterprises could be considered as given. Therefore, YEE, by means of FAIRWIS, will develop an environment suitable for the experimental development of flexible, dynamic, and inter-organizational business ventures for simulation and training purposes.

This means setting up a laboratory marketplace where supply and demand could meet and develop activities to exploit emerging business opportunities in a domain-oriented and seamlessly integrated knowledge sharing and collaboration space. Therefore, the FAIRWIS business integrator prototype would be applied to a virtual forum having an audience of many laboratory SMEs.

FAIRWIS would be in charge of the design and management of the on-line environment aimed at supporting the development of dynamic cooperation among laboratory enterprises. It would create the humus to enable the development of laboratory virtual enterprises, an environment similar to a holonic system. In this simulated competitive environment, enterprises (having competitive and complementary competencies) would be able to efficiently and effectively integrate themselves.

By means of FAIRWIS, YEE would be able to set the rules and the standards for any cooperation and to provide added value services (Barbini 2001). It would, in addition to managing the environment, propose customizable methods and tools to efficiently set-up a virtual enterprise (e.g. communication protocols, data sharing methods, workflow design schemas, best practices).

The resulting system can function as an incubator for new virtual organizations and to generally allow an environment based on mutual trust and common values by combining "human contact" and Internet technologies. However, this is not sufficient for incubating virtual organizations. Therefore the FAIRWIS business integrator will furthermore supply a full range of high value services to support the creation, management, and dissolution of the cooperation venture [Porter, 2001].

6. Educational Platform

Today, students are "passive" (tutors "push" contents to learners); present learning paradigm is mainly a teaching paradigm, learners having a passive role. FAIRWIS will allow a major shift toward a learning paradigm: it will be a system supporting and allowing distributed cognition, articulate learners, peer-to-peer learning, and incremental enhancement of information spaces by a community of practice (Fischer 2001) (Mason 1999).

The proposed system would:

- Provide high quality, i.e., peer reviewed professional business publications and education support utilizing existing explicitly published professional business materials, business textbooks, business tutorials etc. It will support professional business authors and business learners to publish in and learn from the collections of professional business communities and organizations (universities, research institutes etc), where young and potential future business professionals can learn from traditionally published material as well as ad hoc acquired or late breaking professional business knowledge.
- Support multi-lingual and semantic access to collection of materials. This means that students would be enabled to utilize their familiar native language as well as the semantic to search and browse the content of professional business publications and business learning materials. The system will therefore generally support access, i.e., information retrieval searching, filtering, and browsing activities on both the semantic and the syntactical level. This means professional business authors, teachers, trainers, and students will be enabled to utilize content-oriented business subject classifications, business thesauri, and business ontologies to search and browse the content of professional business publications and business learning materials.
- Support professional business publishing and learning communities based on the user's roles in their communities and organizations, so that individual students would find themselves naturally supported by both their peers and by the accumulated knowledge of their professional business community via applications of various advanced knowledge management techniques.
- Support the basic education management functions, such as checking which materials a learner has studied, mastered etc. as well as helping learners to find experts, peers, and teachers that can answer his/her questions, as well as allow individuals to track and manage their own personal and professional development.
- Support the modeling and simulated execution of virtual enterprise training scenarios. This means students would be enabled to utilize virtual enterprise modeling and configuration functions to set up laboratory virtual enterprise. The FAIRWIS virtual enterprise simulation and training environment will provide support for semantically modeled and represented domain construction, business process modeling and simulation both on the operational layers of enterprise organization and operation as well as on tactical and strategic layers of general Enterprise management, business development and business integration.

In addition, the foreseen system would allow the creation of a European network of laboratory enterprises belonging to national YEE branches.

6.1 System Functionality

The final version of the software prototype will be developed adopting dynamical web technologies and the most advanced provisioning and security solutions. In particular, the server side of the web application will be implemented through the use of java and perl–based back-office technique. The client side of the application will take advantage of java script controls in order to help the user to type in the correct information. Data regarding the tests and the users will be stored in a database placed in the server itself. Information about users will be kept cryptic in the database in order to fulfill the standard privacy requirements. Data exchange between client and server during the test will be managed using https secure protocol (D'Atri 2002a).

The system is expected to work from the beginning in the expectance of 1000 simultaneous connections. As for content quality and certification, the system is expected to be conform to the certified YEE criteria. A management system will be able of identifying all user's pathways, using a personal ID and password as well as of elaborating statistical data and results to allow individual credit grants.

YEE would take care of the guidelines for the management of the International Property Rights (IPR) on the published contents.

Moreover the exploitation and the diffusion of this long-distance education, training and accreditation project will allow tutors to monitor students' training and competencies acquisition quality.

The usage aspects and advanced content and knowledge management methods must be supported. Thus we will focus on the development of a comfortable working environment for administrators and the companies which are customers of the virtual enterprise environment. Moreover, the use of XML and RDF as the underlying content and knowledge representation languages, will both ensure the complete scalability of the system and contribute to the standardization as the principal aim of international organizations. The framework will be designed to be generic, i.e. to be applicable to other content domains, types of applications and users. Hence, special emphasis will be placed on the scalability of the system, the development of generic tools and portability of the project results (models and software) for other types of applications in the area of XML and RDF based Content/Knowledge Management.

6.2 Benefits

The proposed system will represent a major shift learning/training support by:

- Supporting active learning and training. The FAIRWIS learning approach will be very learner-oriented: instead of teaching pre-defined contents, the system will allow learners to specify their own needs, objectives and commitments in order to receive true just-in-time, customized and personalized training. Hence, learning will be much more self-directed, answering individual education needs, and avoiding the limitations of current systems, based mainly on pre-defined options. In this framework, teachers role shifts from being the conduit through which information is transmitted into being a tutor, a facilitator, or a coach.
- Providing ICT -related training, in order to enhance the usage of these technologies and, hence, youth employability.
- Enabling laboratory organization to effectively manage their knowledge. Knowledge is as more organizational as more it is shared and distributed within the organization. FAIRWIS will allow each user to find what he/she is looking for and will deliver him the knowledge

formatted and "packaged" in the way he can better recognize and learn it. The system will enable users even to found what they don't know but might be helpful for them.

7. Conclusion and Further Research

FAIRWIS, by using and exploiting the potential of ICT in the context of laboratory virtual enterprise will deliver an innovative learning/training service to YEE students. The way to reach the goal is to enhance the existing electronic publishing frameworks with respect to professional business knowledge acquisition, annotation, indexing, access, and assistance services of already existing digital library technologies to support professional business teaching and training material publication, distribution, and usage, i.e. learning and training scenarios based on the knowledge acquisition, reviewing, annotation, indexing, publishing, distribution and reuse techniques developed in the domain of information technology supported knowledge management.

Although the present goal of the FAIRWIS project is to help young and future European business professionals to start their initial as well as their life long self learning and training for working in professional business domains, the system may also be applied in the near future to the life-long learning needs of Small and Medium Enterprise managers.

Indeed, SMEs internal flexibility and the rapid evolution of the environment in which they operate force the managers to continuously update their professional skills and to develop new competencies, adequate to the role and the activities they have to perform. Hence, SMEs need to have flexible staff able to take on a variety of roles depending on the circumstances. This allows them to ensure that all tasks can be covered when different needs arise, and also ensure that labour costs – probably a high percentage of their overhead – are employed efficiently. This also puts a time pressure on anyone wishing to learn in work time, and results in the desire to spend only as much time as is truly necessary on learning. To summarize SME's learning needs, it is possible to say that they need specialized and customized contents, just in time and just enough.

FAIRWIS is supposed to offer to SMEs a learning/training environment which is scalable, modular and highly customizable. In addition, it would allow SMEs to manage in a more efficient way their knowledge and to make explicit and reuse it. The flexibility and high customizability of the proposed system would make of it a state-of-the-art solution for all SMEs willing to improve their managers and workers skills.

In addition, the FAIRWIS resulting system prototype is expected to become an added-value integrator for SMEs over the Internet and would therefore foster advanced business intelligence behaviours of SMEs.

Education Web Site Review and Redesign

Dr. Cathy Cavanaugh, Curriculum and Instruction, University of North Florida, USA. ccavanau@unf.edu

Abstract: Web sites are important for schools to support teachers, administrators, counselors, students, parents, and the community. Redesigning a school's web site can become a complex process and requires careful planning. Studies with web users (Yale Style Guide, Nielsen, Siegel) have produced work that informs school web site revisers of ways to make a site more usable and enjoyable. The US government and the W3C consortium have accessibility guidelines for web sites to assist site reviewers in adapting their site so users of all abilities have equitable access. A school must reconcile time and budget limitations with the need to serve a diverse audience. This paper offers guidelines and tools for streamlining the process of web site review and redesign. Recommendations address the web site redesign team and their roles, supporting the process, identifying the site's purposes, user surveys, content audits, task lists, storyboards, color palettes, style guide, usability and accessibility.

Web sites are becoming increasingly important for schools as support for teachers, administrators, counselors, students, parents, and the community. According to the Webb66 online school web site directory, over 13,000 of the nation's 108,000 schools have web sites. Jamie Mackenzie (1997) offers four reasons for maintaining effective school web sites. Reasons include introducing visitors to the school, pointing students to useful web resources, publishing student work, and collecting data on curriculum projects. Developing or redeveloping a school's web site can become a complex process and it requires careful planning. Judi Harris (1997) suggests exploring who will use the site, what information users will require or appreciate, and maximally useful ways to present the information. Years of study with web users (Yale Style Guide, Nielsen, Siegel) have produced an extensive body of work that informs school web site revisers of ways to make a site more usable and enjoyable. The US government and the W3C consortium recently released accessibility guidelines for web sites that will assist school web site reviewers in adapting their site so users of all abilities have equitable access. School web site review and redesign may be a limited, target process for making basic improvements and updates, or it may be an ambitious complete overhaul. Extensive web redesign projects can be facilitated using summer writing teams, grants, and class projects done by high school or college web design students.

The following tools are presented sequentially as guidelines to assist in the school web site redesign process. Schools have unique needs, capabilities, and characters, and each school's uniqueness is reflected in its web site, as it is in the redesign process. Schools have widely varying resources to commit to web site redesign. Therefore the tools presented here should be considered a menu of options, any of which can be used to streamline the process.

1. Site redesign team

1.1 Menu of site revision team members

School/district tech coordinators	Technical aspects of changing and adding files, server support for interactive elements, permissions, presence of tech support pages
Graphic artists/designers	New logo or navigation elements, layout of pages
Teachers	Design of class pages, curriculum pages, teacher info pages
Students of various levels	Interest in look and feel of site, success I navigating site
Parents	Rating usefulness
Club/sport sponsors	Design of club, team and group areas

Administrator	Approvals and permissions, design of admin area
Clerical/secretarial	Design of pages related to policies, procedures, updating handbooks, menus, schedules, news
Partners in education	Design of appreciation pages
Businesses, organizations	

1.2 Support needed by revision team:

Support includes: time and place to meet together and with groups for focus discussion and testing, flexibility in releasing students and staff to assist, access to networked computers, method of making changes on test server, budget for new software, cameras, and paper.

2. Site purposes

2.1 Identify purposes of our school web site: decide who uses the site and why, then design for them.

Purposes may include: recognizing student achievement, posting collaborative student projects, organizing curriculum resources for teachers and students, organizing information for staff, introducing visitors to the school, introducing prospective students to the school, providing information to parents, providing information to businesses and families new to the area.

2.2 Survey users about their needs and preferences:

Ask "What do you like most about using the web?" and "What do you like least?" Use a questionnaire to gauge the importance of different web features, or to judge the current school site. Consider: What's good and what's not working about the current site? Who are typical users and their age, ability, and technology? What actions do users take at the site? How should users perceive the site: fun, friendly, professional? How can the school show its uniqueness? What sites do users like and why? What current content will be kept? How will the content be structured (information design)? What would be the first 3 things you would change about the site? What aspects of the current look do you want to keep? (Goto & Cotler, 2002)

Design principles relate to the visual elements, layout, and navigation. The following general principles lead to a more user-centered site (ED's Oasis, 2002). Pages are clearly titled. Graphics and art are functional/relevant. Icons clearly represent what is intended. Alternate navigation methods are present. The online resource accommodates multiple modalities and learning styles. Extensive scrolling is not required. Advertising is absent, minimal or is useful if present. A link back to the home page is provided. Text and colors are legible. There is a site map available for easy navigation. The site employs consistent design elements throughout. Pages are free from logical and language errors. There are useful headings and subheadings on the page.

Usability standards increase a site's readability, ease of use, and user satisfaction. Most sites and their users benefit from adhering to these standards. The site is easy to navigate. Information is available in more than one format. The pages load quickly. Text is easy to read, and simply written. Site organization is logical. Links are current and descriptive. Links to additional resources provide related information or examples and support learning objectives. Pages are free from frames requiring scrolling. The page does not require special plug-ins or programs to run. The site limits elements that might create accessibility issues (sound without text, graphics, buttons screen reader can't read) (ED's Oasis, 2002).

The educational value of a school website is judged in terms of appropriate content for its purpose and audience. The purpose of the site is evident and appropriate. The author/sponsor of the site is indicated. The author/sponsor of the site has adequate authority/credentials. The author/sponsor can be contacted. Information is educational, objective and true with limited bias. Is there a date that tells you when the page was made? Links to more information are provided. The site clearly guides users as what they can do there and how. Student communications and contributions are screened before being posted to the site. The arguments are supported and the sources of information are documented.

Give all users opportunities for input by asking questions such as: What information is present in the site that is not needed? How should information be grouped or organized better? What information is missing from the site that would be useful to users? What other suggestions do you have for improving the site?

3. Web Site Redesign Profile

Create a redesign profile for the web site to guide the redesign work. Include the site goals, the needs and preferences of the audience, the main redesign issues and goals, the tone desired for the site, the technical and time scope possible for the redesign, the long term site maintenance plan, and the abilities of the project team (Goto & Cotler, 2002).

4. Learn about other school web sites

Use a web search to study the web sites of other schools similar to yours. Choose a few sites for users to rate in comparison to yours: What do these do better or worse than ours? What is easier and harder at these sites?

Audit of existing site content (Goto & Cotler, 2002)

Section: Home page *index.htm*			
Item	Description	Importance (1=low, 5=high)	Action (+ to keep, – to delete)
Intro text	2-3 lines of school overview	1	
Principal message	1 paragraph of welcome	5	Incorporate into overview or move to principal page
Mascot logo	Black line drawing of school symbol	2	Improve quality
Navigation buttons	Graphical links to grades, reading, sports, calendar	1	Revise to reflect new theme and content
Contact	3 lines of address, phone and email	1	
Animated message	GIF animation of seasonal image	5	Increases maintenance and load time

5. Task list

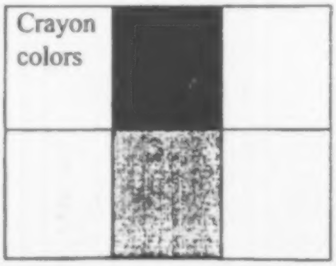
Develop a task list, showing priority items, responsible people, deadlines, and completion. Items to include: poll users about needs and preferences, periodically report changes to users, demo at staff meeting or Open House, add screen capture to newsletter, update images and logos, add interactivity or a feedback form, add common school forms, create form for teachers to add class news and assignments and sport scores, add student gallery, update links to curriculum resources, add VR/panorama of new media center and nature center, test new features, or add PTA newsletters.

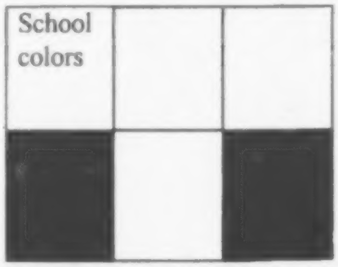
6. Site planning

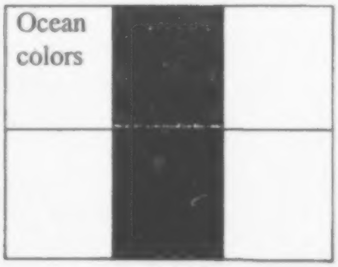
6.1 Site map

Create a site map using diagramming software or graphics software such as Inspiration, Visio, or Freehand. Plot out the pages and links. Ask for feedback, additions.

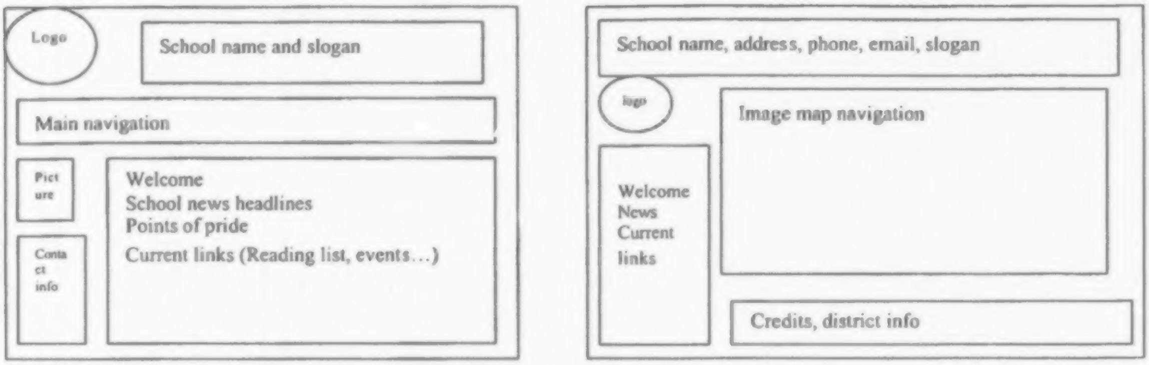
6.2 Compare color palettes







6.3 Storyboard possible page designs



Logo
School name and slogan
Main navigation
Picture
Welcome
School news headlines
Points of pride
Current links (Reading list, events…)
Contact info
School name, address, phone, email, slogan
logo
Image map navigation
Welcome
News
Current
links
Credits, district info

7. Style guide

Develop specifications for common aspects of pages.

- Colors for titles, text links, backgrounds, borders
- Text: use of formatting such as bold, quotations, heading sizes, fonts
- Images: file formats, padding, school and district guidelines for students and student work
- Content: copyrights, permissions, requirements and prohibitions

College Website Review and Revision for Accessibility

Terence W. Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, Jacksonville, FL USA.
tcavanau@unf.edu

Abstract: Websites are becoming increasingly important for colleges as support for faculty, administrators, counselors, students, parents, and the community. A primary factor when restructuring, updating, or creating a college site should be making sure that the site will be fully accessible. Restructuring a college's website to ensure accessibility can become a complex process and it requires careful planning and knowledge of accessibility issues. The US government and the W3C consortium has accessibility guidelines for websites that will assist website reviewers and designers in adapting their sites so all users have equitable access.

Need

An education college website should have as its mission to recruit, support, and inform current and future students and faculty about the college and the profession, while at the same time modeling educational design concepts and ethical educational behaviors. An analysis of a local College of Education website determined that the site had become outdated, did not fulfill its mission effectively, and was not compliant with accessibility guidelines. For a college that has deaf studies and special education programs, a priority was expressed that the college's site be accessible to disabled users. To that end the college wanted to ensure that its website would model proper application of accessibility guidelines as promoted by the W3 Commission and the US government's Section 508 of the Rehabilitation Act concerning Electronic and Information Technology.

Guidelines

Currently there are two major "players" in the structuring of accessibility guidelines for web-based materials in the US, the United States government itself with section 508 of the 1998 Rehabilitation Act, and the World Wide Web Consortium's Web Accessibility Initiative.

Section 508 of the Rehabilitation Act was put into place to help eliminate the barriers in accessing information technology, to make all such information available for people with disabilities. While this law currently only applies to Federal agencies when they develop, procure, maintain, or use electronic and information technology, it is to a school's advantage to make information about that school as accessible as possible. Additionally while not currently required, it is not beyond expectations that state governments will also make these guidelines a requirement for state web sites as well as public schools, colleges, and universities. A web site will be in compliance with the 508 standards if it meets paragraphs (a) through (p) of Section 1194.22 (see Appendix A). The World Wide Web Consortium has developed its own fourteen guidelines (see Appendix B) concerning web accessibility. Within each of these guidelines are a number of checkpoints, which have priority ratings from One to Three. Each checkpoint has a priority level assigned by the W3C Working Group based on the checkpoint's impact on accessibility. According to the W3C at a minimum, for accessibility, a web site *must* be designed to meet all Priority One elements or some groups of people will find the site impossible to access. Satisfying all Priority Two elements *should* be done to remove the most significant barriers to accessing a web site. The Priority Three elements are an optional set that *may* be addressed to ensure that there is improved access to the web documents. By following the W3C web accessibility guidelines, sites can have an accessibility rating of "A," "AA," or "AAA." This rating system is based on the level of conformance that the site achieves. A conformance level of "A" indicates that all Priority One elements are satisfied, "AA" shows that the site is satisfying all Priority One and Two elements, and "AAA," being the highest level, with all Priority One, Two, and Three checkpoints in compliance. As an example, to achieve the minimum conformance level of "A," a site must meet all of the following priority one guidelines:

- Provide content that conveys essentially the same function or purpose as auditory or visual content;
- Ensure that text and graphics are understandable when viewed without color;

BEST COPY AVAILABLE

- Clearly identify changes in the natural language of a document's text and any text equivalents;
- Ensure that tables have necessary markup to be transformed by accessible browsers;
- Ensure that pages are accessible even when newer technologies are not supported or are turned off;
- Ensure that moving, blinking, scrolling, or auto-updating objects or pages may be paused or stopped;
- Ensure that the user interface follows principles of accessible design: device-independent access to functionality, keyboard operability, self-voicing, etc.;
- Use features that enable activation of page elements via a variety of input devices; Provide context and orientation information to help users understand complex pages or elements; and
- Ensure that documents are clear and simple so they may be more easily understood (Web Content Accessibility Guidelines 1.0, 1999).

Self Evaluation

The next step in the college's web site revision process was to find out specific ways that users felt the site was not fulfilling its mission. The initial part of this investigation included a series of interviews with faculty members and students to find out what they found useful about the current site, problems they had, how they felt the site could be improved, and where the college's web site was not following accessibility guidelines. From the initial analysis concerning accessability of the site it was determined that improvement was needed in alternative text tags, use of framesets, and identification concerning the languages and html formats on the individual web pages. Each phase of the redesign was reviewed and approved by the college's technology committee using mock up web pages, navigational concept maps, survey and interview results, and accessibility needs. As professional educational institutions all colleges of education should achieve accessibility by meeting W3C and ADA compliance standards to reach at least the "A" rating put forth by the W3C commission for accessibility.

Accessibility Tools

Research was undertaken in finding tools to evaluate the site to improve accessibility. There are several tools available, many of which have no cost, and as we had a limited budget we limited the choice of tools to the no-cost options. Some of the free tools that were examined included Bobby from CAST, HTML & CSS Validator from W3C, A-Prompt from the University of Toronto, and the 508 Accessibility Suite for Dreamweaver. An excellent listing of over thirty different tools to assist in evaluating and repairing sites for accessibility is the Evaluation, Repair, and Transformation Tools for Web Content Accessibility from the W3C Web Accessibility Initiative at http://www.w3.org/WAI/ER/existingtools.html.

While each of the tools reviewed had their own advantages, A-Prompt was chosen as the evaluation tool, because of ease of use and because of its assistance in identification of accessiblity issues, as well as in guiding and assisting in their correction. A-Prompt (for Accessibility Prompt) is a software tool designed by University of Toronto's Adaptive Technology Resource Centre (ATRC) and the TRACE Center at the University of Wisconsin to assist web authors in improving the accessibiltiy and usability of HTML documents by evaluating Web pages for accessibility barriers and then providing developers with simple methods to make the needed changes to ensure accessiblity. A-Prompt makes its evaluation and repair based on accessibility guidelines created by the Web Access Initiative of the World Wide Web Consortium or the US Rehabilitaion Act 508 guidelines. Users of A-Prompt can set which guideline they would prefer to follow and to what level.

Restructure

The actual design change for accessibility of the college site was done at the end of the restructure process. It was done at the end because of the number of persons who were working on and evaluating the site concerning structure and content. Since the focus, at that time, was on content, the authors did not need special training to make sure that their changes were following compliance standards. To assist in the development of new pages, web page templates were created that were already compliant for accessibility. Once all the college's pages had been checked for content and design, and all new pages created the entire site was evaluated using the A-Prompt software. In discussions between the site designers and the administration, the W3C guidelines were used and the site was restructured to achieve the "AAA" rating.

Once all pages had been filtered through the A-Prompt tool and the site was compliant a series of tests were undertaken to ensure that accessibility had been achieved. These tests included using a variety of standard monitors and browsers, then again checking the site using specialized accessibility tools such as screen readers, screen enlargers, and accessing the site through a universal access station. The final phase of the evaluation involved requesting students with disabilities to access and evaluate the site.

Conclusions

College sites should provide information to *all* prospective users. This information can include the programs that are available and the number of hours and courses required for programs, images or photographs of students and facilities, and any other relative information. But a college must also make sure that its information is accessible by all. While a committee of the college may direct the maintenance and structure of the college's website, that committee needs to have someone who is aware of online accessibility issues, to ensure that the college's site either achieves or maintains accessibility compliance. Also since at many colleges numerous persons can post or change web pages, the college site should periodically be reassessed for accessibility compliance and training made available for all college web authors.

Appendix A

508 Standards: Section 1194.22 Web-based intranet and internet information and applications.

(a) A text equivalent for every non-text element shall be provided (e.g., via "alt", "longdesc", or in element content).

(b) Equivalent alternatives for any multimedia presentation shall be synchronized with the presentation.

(c) Web pages shall be designed so that all information conveyed with color is also available without color, for example from context or markup.

(d) Documents shall be organized so they are readable without requiring an associated style sheet.

(e) Redundant text links shall be provided for each active region of a server-side image map.

(f) Client-side image maps shall be provided instead of server-side image maps except where the regions cannot be defined with an available geometric shape.

(g) Row and column headers shall be identified for data tables.

(h) Markup shall be used to associate data cells and header cells for data tables that have two or more logical levels of row or column headers.

(i) Frames shall be titled with text that facilitates frame identification and navigation.

(j) Pages shall be designed to avoid causing the screen to flicker with a frequency greater than 2 Hz and lower than 55 Hz.

(k) A text-only page, with equivalent information or functionality, shall be provided to make a web site comply with the provisions of this part, when compliance cannot be accomplished in any other way. The content of the text-only page shall be updated whenever the primary page changes.

(l) When pages utilize scripting languages to display content, or to create interface elements, the information provided by the script shall be identified with functional text that can be read by assistive technology.

(m) When a web page requires that an applet, plug-in or other application be present on the client system to interpret page content, the page must provide a link to a plug-in or applet that complies with §1194.21(a) through (l).

(n) When electronic forms are designed to be completed on-line, the form shall allow people using assistive technology to access the information, field elements, and functionality required for completion and submission of the form, including all directions and cues.

(o) A method shall be provided that permits users to skip repetitive navigation links.

(p) When a timed response is required, the user shall be alerted and given sufficient time to indicate more time is required.

Appendix B

W3C Accessibility Guidelines

1. Provide equivalent alternatives to auditory and visual content. Provide content that, when presented to the user, conveys essentially the same function or purpose as auditory or visual content.
2. Don't rely on color alone. Ensure that text and graphics are understandable when viewed without color.
3. Use markup and style sheets and do so properly. Mark up documents with the proper structural elements. Control presentation with style sheets rather than with presentation elements and attributes.
4. Clarify natural language usage. Use markup that facilitates pronunciation or interpretation of abbreviated or foreign text.
5. Create tables that transform gracefully. Ensure that tables have necessary markup to be transformed by accessible browsers and other user agents.
6. Ensure that pages featuring new technologies transform gracefully. Ensure that pages are accessible even when newer technologies are not supported or are turned off.
7. Ensure user control of time-sensitive content changes. Ensure that moving, blinking, scrolling, or auto-updating objects or pages may be paused or stopped.
8. Ensure direct accessibility of embedded user interfaces. Ensure that the user interface follows principles of accessible design: device-independent access to functionality, keyboard operability, self-voicing, etc.
9. Design for device-independence. Use features that enable activation of page elements via a variety of input devices.
10. Use interim solutions. Use interim accessibility solutions so that assistive technologies and older browsers will operate correctly.
11. Use W3C technologies and guidelines. Use W3C technologies (according to specification) and follow accessibility guidelines. Where it is not possible to use a W3C technology, or doing so results in material that does not transform gracefully, provide an alternative version of the content that is accessible.
12. Provide context and orientation information. Provide context and orientation information to help users understand complex pages or elements.
13. Provide clear navigation mechanisms. Provide clear and consistent navigation mechanisms – orientation information, navigation bars, a site map, etc. -- to increase the likelihood that a person will find what they are looking for at a site.
14. Ensure that documents are clear and simple. Ensure that documents are clear and simple so they may be more easily understood.

Web/CD Hybrid model for the Distance Learning Environment

Terence W. Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, Jacksonville, FL USA.
tcavanau@unf.edu

Abstract: The limited bandwidth available, slow modems, and connection issues hamper the delivery of software and multimedia in the online class environment. A possible solution is adjusting from a web-based distance learning class to a Web/CD hybrid delivery method, which uses the advantages of each separate delivery format. Creating a Web/CD hybrid course not much different than creating a distance learning course. The online course component can access the CD for audio, video, and other large files to eliminate download times. The Web/CD hybrid format has some of its own issues such as computer platforms, CD development, and distribution.

Web/CD Hybrid model for the Distance Learning Environment

The goal of this paper is to provide distance education instructors with an alternative or adaptation to the delivery format that should assist in overcoming one of the greater problems with distance learning, that of bandwidth. The use of the web and with supporting interactive CD delivery format is one that can alleviate many connection and bandwidth issues while at the same time providing better instructional materials for students. In most course environments it is possible to effectively integrate quality CD ROM materials into the online learning environment.

It seems that all schools and colleges across the nation are adding distance learning courses. Many state university systems are under the directive to encourage institutions and their faculty to embrace distance learning. However, the problem that exists at the forefront is that many institutions do not have access to a reasonable range of technologies (Hurst, 1997). While it would be ideal to acquire all the needed technology for all institutions, there still currently is not acceptable telecommunications bandwidth for voice, video, and data with a strategy to increase bandwidth as demand requires. The problem is that these types of digital files are very large, and they require connections with tremendous capacity to transmit quickly and effectively. The transmission capacity of the connection is referred to as the bandwidth (Barron, 2002). It is the technological issue of bandwidth that placed many of the limitations on the distance learning experience (Hernandez and others, 1998). The limited bandwidth available, slow modems, and connection issues hamper the delivery of sound, video, and graphics (Kerka, 1996). This bandwidth issue remains today, with no quick solution in sight, but through the use of alternative deliveries and integrating technologies it is possible to overcome many of the bandwidth issues that prevent the delivery of multimedia and other bandwidth intensive technologies.

In assessing my own students in distance learning and web enhanced classes I find that the students access the internet based materia l through one of three standard methods, either through the campus network if they live on campus or by cable or dial up modem. One of the multimedia elements that I was trying to include with these courses was a video that when converted to digital format became a 147 megabyte mpeg video. While accessing this video through the network was usually not an issue, except during peak network time, accessing and downloading the video through the internet can vary from about 30 seconds on a cable modem to up to 400 times that for a standard dial up modem but took less than 2 seconds to start from a CD (Daniels et.al. 2000, National Academy of Sciences 2002 and Barron 2002).

In Hurst's 1997 "Assuring Equitable Access: A Distance Learning Vision for Florida" the authors sate that it is important to remember that technologies are merely tools, and that these tools must be adjusted for the "content, the teaching/learning style of the instructor and the learning style of the student," and that this " argues for multiple methods, both low-tech and high-tech, of delivering instruction for distance learning." For some learners this can be text (such as books), for others, such as visual or aural learners, courses need to support and make available options like video, video and audio conferencing, and other image or sound based delivery options.

As an ideal case, distance learning educators would like to be able to deliver high quality and high impact multimedia, incorporating digital audio and video, and software to students. Currently in the US there are over 6 million homes with broadband access, but that actually only accounts for about nine percent of the households, leaving the rest accessing as slower speeds (NCTA, 2001 & Cisco, 2001). When downloading high bandwidth files, the students find that the time it takes to download becomes excessive or while downloading they have line errors or their internet service provider cuts them off because of the amount of "inactive" time. Another problem that commonly occurs is that when downloading or playing such media, more students will attempt to access the files than the server can handle. The question then develops, is it possible to add such "high bandwidth" media without adding burdens to the student's connection speed or the colleges local course web server? One possible solution is adjusting a distance learning class from being totally web-based delivery to a Web/CD hybrid delivery method. While streaming video and audio are available, they often don't provide the quality desired or needed for the intended educational use. Streaming media also still depend on the connection speed and the bandwidth available to the user, and require specialized servers which may be limited on access and space. Through the application of web delivery with CD ROM enhancement it is possible to overcome most problems while providing students with better access to the educational materials. An additional feature of this format is that it allows instructors to make certain materials, such as videos, presentations, and readings, available off line, so students can have access to the material even when they don't have internet access.

Each delivery format, web only or CD, has its own advantages. An online web environment allows instructors to have a course space that can be easily updated, it can track where and how long students used it, and it can allow students to input information into discussion boards, online tests, or whiteboards to which the instructor can respond. A course based CD can provide full screen, non-delayed extended video and audio, and it can provide students with material that can be access and reviewed offline, or played on devices other than a computer, such as a DVD or CD player. The Web/CD hybrid environment by melding the two delivery formats, is taking the advantages of both systems, while eliminating many of each formats shortcomings.

The process of creating a Web/CD hybrid course is no different than creating a distance learning course, with the exception of perhaps fewer limitations. One method would be to take an existing distance learning course and determine which components are "high-bandwidth," large file size, or complex components. Transfer these high-bandwidth files off the web server and place them on a CD, which is distributed to the students. Another method would be to take a course which is currently supported by a CD and determine where it could use online support for interactivity, assessment, or currency. Then create an online course site to support those gaps and put links onto the course's CD that directs students to the online environment. The last method would involve designing the course from the beginning with the hybrid model in mind. With the hybrid design instructors would be placing the material that needs updating for currency online along with other material such as assessments, outside readings, assignments, and discussions. The CD for the course could contain continually used readings, audio and video files, and other large files such as software and tutorial programs. The online course environment then has links that call up the files on the user's local computer CD drive and to play or run the files at that computer.

Most of the online course space environments, such as BlackBoard and WebCT, support the use of local CDs. It is even possible to get software that allows instructors to create the necessary code to give students interactive access from regular web pages. On the instructor side, when creating a course page in the online environment, the course instructor sets up a link in the course management system to access the material offline. The link from the course management system to the file on the CD, includes the path to the file on the CD that is to be accessed offline. The course management system creates a link to that file and indicates, usually with a CD icon, that a CD will be necessary in the computer to access the file. A student then moving within the course site clicks on the link to the CD's file like any other link in the environment to gain access to the file. This process requires the students to identify the name or letter for their CD drive to the course management system, and to place the course CD into the local computer's CD drive.

The Web/CD hybrid format does have some of its own issues. There is an additional set of instructional steps necessary for the environment to work. Students will need additional instruction concerning how to set their personal preferences for their computer's CD drive. For many instructors, the CD itself will be an issue, especially if he/she has never created one before. Once all the files have been gathered, keeping in mind there is still a 650 megabyte limit for file space, a disc master must be created. If students will access the material on more than one computer platform, a cross platform CD will have to be created. The CD will then need to be duplicated and distributed to the entire online class. Most courses will not have enough students to justify copying the master CD at a CD pressing plant, so it will be necessary to duplicate the CDs on campus using a standard CD burning drive or small scale CD duplicating machine. It is important that students have access to the files on the CD from the beginning of the course. Therefore the CDs must be created before the course begins. If the course's students don't have an initial face-to-face meeting a distribution system will need to be developed.

I have been using the Web/CD hybrid for both my distance learning courses and my web enhanced courses over the past few years. As an example I have my online students accessing a video file that is over ten minutes long, without download time issues. They can play the video in their computers or watch on their DVD players. I have made improved use of other programs such as PowerPoint. Web based PowerPoint presentations often are unable to use the full features of the program, such as interactivity or associated files. When the students use the program and file locally they are able to fully interact with tutorials I created that include interactive elements with video supports. Another example that worked very well was when I included FrontPage Express as a program on the course CD. The software program itself required other files to run, so it would not work if I put the executable file in the course web space. The program file and its other required files were put on the CD in the same directory. All students then were able to have the necessary software, working with the same version (often important for directions and to help with support), whether they were working online or offline. Another advantage that I have found of the Web/CD hybrid delivery is including other programs such as viewers like Word viewer, PowerPoint viewer, and Adobe Acrobat Reader, and sample software programs for students to review or use. This way if a student didn't have a specific reader to access the web or CD distributed file he or she could go to an online "programs" page and click the link to the CD to install the necessary programs from the CD on the local computer.

The application of the Web/CD hybrid design can not only help the students, it can also assist us as educational professionals to meet our own standards. By adapting the distance learning courses we as teachers are meeting the ISTE teacher standards for Planning and Designing Learning Environments and Experiences, and Teaching, Learning, and Curriculum (ISTE, 2000). We would be meeting these standards because by using the Web/CD Hybrid model we would be developing resources to support effective learning opportunities for online instruction for various learning styles, and would be implementing technology-enhanced plans, as the process assists in overcoming issues in application of technology, due to bandwidth and connectivity. The Web/CD hybrid process also supports the administrator standards of Productivity and Professional Practice, and Learning and Teaching (ISTE, 2001) by enhancing and supporting curriculum with multimedia and other high bandwidth technologies, and providing technology tools that can increase the capacity of existing online educational systems. This hybrid model also supports the NCATE standards by providing an answer to their distance learning question, by providing a technology support that helps prevents breakdowns and interferences with distance learning delivery (NCATE, 2002).

Abstract: This paper discuss the changing paradigms in Taiwan's Academic learning, with the advanced network that has been implemented for the broadband application, e-learning has been taking advantage to utilize the network to demonstrate the demands. The success of the National Broadband Experimental Network infrastructure that Taiwan government has sponsored was the key factor that made all applications possible. Various methodologies were deployed to help strengthen the network architecture. GigaPOPs and universities helped to manage the operation as well as implement specific technology that support specific needs. The evolution of the broadband network in Taiwan was a success after different phases of deployment; the changing paradigms not only apply to the application but also apply to the network as well. The recent research work has been conducted on NBEN included: Web-based circuit provisioning; Traffic management, measurement, analysis & reporting; Routing registry, proxy hierarchy & maintenance; QoS, DiffServ & IPv6 and Multicast, video conferencing & showcase. These successful research results demonstrated the infrastructure capable of supporting advanced research and educational applications which is the ultimate goal for this broadband network.

Introduction

The idea of e-learning is nothing new, which has been implemented in many different education institutions, ranging from elementary schools to universities. Some use interactive multimedia to attract attentions from youngsters; some upload the instruction materials to the web so students can preview before the class and review after lectures. They all have one thing in common, that is to utilize the newest technology to deliver educational contents.

One advanced network that origins from National Science Council in Taiwan is National Broadband Experimental Network which has been established since 1999, it includes most of the major universities as GigaPop sites to support the continues effort on education. This network serves an important role as platform to host various experiments; also it provides multiple experimental broadband applications.

This paper discusses the deployment of the network, its structure, its phases of integrations to achieve high bandwidth and the current activities.

The motivation of the experimental net

This project started in 1999, the goal was to establish a broadband network that can support all the experiment that needs to be conduct on, with proper management, the experiment can interrupt the operation on the network, the reason behind this is that normally some experiment can only conduct in a lab, due to the unknown impact happened to the network. Some experiments, however needs extensive challenge that may cause the unstable of the network. This project was designed so different experiment can be conduct with proper procedure so all can expect without concern of the network operation.

One application that was serious take advantage was the e-learning, unlike the research experiment that fully use the network that cause the downtime of the network, we need a broadband network to experiment the impact of the multimedia teaching, this included the effective of material transfer, the effect on the receiving end, these apply to all the level understanding between the different ages of students.

The Development of NBEN

NBEN is a project of continuation to promote the backbone network bandwidth and provide an experimental platform for broadband network technology. It aims to perform research for institutions and industries, in addition, it seeks to support service providers and compete for long distance broadband network for fiber optics, linking each region with high-speed network.

In addition, it is a platform for advanced technologies such as Multicast, Differentiated Service, Ipv6. This project is a unit under National Telecommunication Program to work with 'wireless network' and 'broadband network' to mutually support and actively educate and train for the needed talents.

In order to provide quality services for the support of National Telecom Development Program, this project also work with National Science Council to promote the applications as well as assisting the neighboring higher educational institutes in each region to have better access to the networks. Currently the coverage includes most major areas in Taiwan including Taipei, Tao-Yuan, Hsin-Chu, Cha-Yi, Tai-Nan and Kao-Shoung. National Broadband Experiment Network has the purpose to serves the upper hierarchy; it provided direct connection to the network.

The backbone and the equipment of this network completed its testing period in June 1999. Since then, GigaPOP has been made available on the experimental platform for research use. The recent research work has been conducted on NBEN included: Web-based circuit provisioning; Traffic management, measurement, analysis & reporting; Routing registry, proxy hierarchy & maintenance; QoS, DiffServ & IPv6 and Multicast, video conferencing & showcase. These successful research results demonstrated the infrastructure capable of supporting advanced research and educational application, which is the ultimate goal.

Current Status

The National Broadband Experimental Network has completed its earlier phase of deployment and currently put the effort on getting the eastern side of the nation up to the speed. Generally speaking, most of the network traffic was generated from the northern part of Taiwan due to the well establish and development in the past years. Currently we have complete building the STM1 to the eastern GigaPop to balance the flow, also to serve as an alternate route. The southern area also has the similar problem due to the lower usage so this current phase will complete the STM1 to the major university in the southern part of Taiwan.

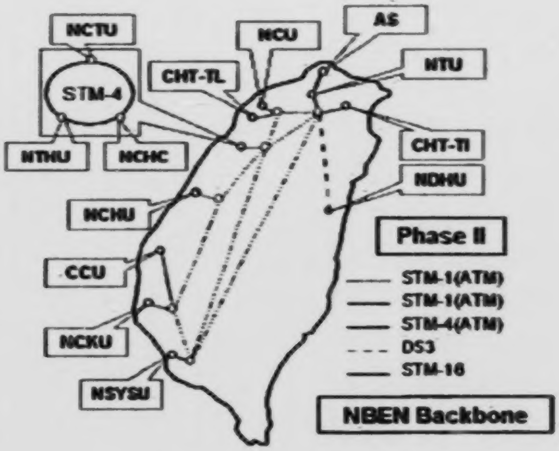

Figure 1 – NBEN Backbone

Active Projects on NBEN

National Broadband Experimental Network not only serves as a platform for the various applications but also

support research project that can be carries out on the network. A task force was formed to study the most needed technology that can be placed on the network and six projects were selected to execute under National Science Council grants, the following is a simple summary of the six projects:

Web-based circuit provisioning project: After the completion of the network, it is necessary to develop a web based system to have the technical management team operate. This project is to have the support team at any time to inquiry the network status, also to have automatically configuration to set the ATM switches, mainly the VP/VC setting.

Traffic management, measurement, analysis & reporting system: This is also a developing system to implement an Active Web based Network Monitor – AW-NETMON. This monitor has the coverage of the wide area network, proactive, alert, and service oriented function. For the wide area coverage, its goal is to cover all the Fore ASX1000 ATM Switch. It also does the monitor on a dynamic basis. For any abnormal activity, it will notify the technical staff, it does some degree of data analysis. Since all the data were capture, this project will build a database to analysis further hopefully to apply the model on the data mining techniques. Once the pattern can be formed, this will prevent many problems, some of the record that has been kept is traffic trace, and abnormal events. The relationship between the monitor stations can be shown on the figure below.

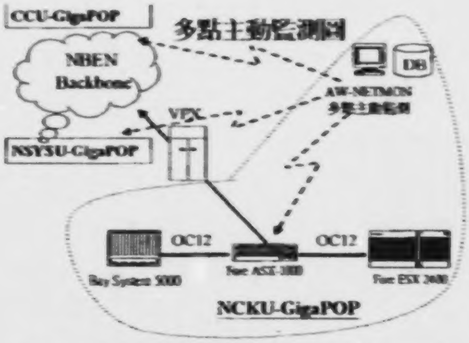

Figure 2 - AW-NETMON conceptive diagram

National Broadband Experimental Network not only serves as a platform for the various applications but also support research project that can be carries out on the network. A task force was formed to study the most needed technology that can be placed on the network and six projects were selected to execute under National Science Council grants, the following is a simple summary of the six projects:

Web-based circuit provisioning project: After the completion of the network, it is necessary to develop a web based system to have the technical management team operate. This project is to have the support team at any time to inquiry the network status, also to have automatically configuration to set the ATM switches, mainly the VP/VC setting.

Routing registry, proxy hierarchy & maintenance project: The goal for this project is to have a complete service plan for all the GigaPop, currently there are more than one network meets at the GigaPop and the routing registry, proxy hierarchy become complicate. By complete this project, research organization can utilize the result to improve network, increases productivity and also have some good control on the traffic usage. Also in this project, some integration was done to simplify the network management methodology between schools.

QoS, DiffServ & IPv6 project: This is a project to better manages the broadband network utilize the techniques of quality of service and others. The basic idea is to satisfy the real time application, the best effort traffic and bandwidth sharing were the idea to be carry out on a PC-based QoS router prototype, hopefully to achieve classification, policy and scheduler functions, the following is the diagram to show the uniqueness of the environment and the expected result.

BEST COPY AVAILABLE

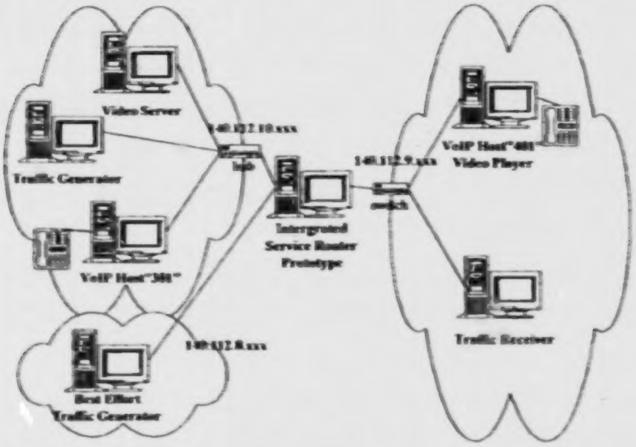

Figure 3 - Differentiated Services Provisioning – the integrated environment

Multicast, video conferencing & showcase project: This is a pilot project to implement H.323 videoconference platform, utilize the high bandwidth, high quality network to benefit all education institutes. The idea of videoconference is common and the effect was not very convincing due to the lower bandwidth in Taiwan. To better satisfy the greater user, this broadband network is a platform to implement. Hosting some of the major domestic conferences as well as international Mega Conference II did some example. Also the same setting has supported to many government-sponsored events all around Taiwan to demonstrate the complexity of the project.

Conclusions

National Broadband Experimental Network has shown the various network technologies and applications that can be done and expend. The future trend has indicated that we need a bigger bandwidth network with higher quality of service to satisfy the demand of education communities. In order to keep this network with the name, National Broadband Experimental Network needs to always increase the bandwidth and expend the user group. Currently the user group has targeted the research and academic organizations, which can be expend to a greater communities. The different regional GigaPop also need to integrate to form high performance network platform with dark fiber. Many newer techniques should also be considered such as multicast; differentiated service to be more of regular service in order to better serves the education communities.

Abstract: The notions of organizational learning and knowledge management share similar lines of thought in leveraging individuals' development to create value for overall organizational intelligence. Although both notions have gained growing attention and interest from academics and practitioners, there have been few attempts in recent studies to collate both notions in order to portray enterprises' intelligent behavior. This study aims to provide a starting point to address the issue of E-learning from a knowledge management perspective, specifically to embrace learning endeavors with knowledge management initiatives. The discussion is expected to achieve three aims: to provide a frame of reference of effective E-learning – for academics to synthesize learning with knowledge management initiatives; for business practitioners to improve the effectiveness of existing E-learning projects with the proposed KM-based aspects; and for national innovations systems theory to be furthered by focusing on the micro learning initiatives at the firm level.

“In a knowledge-based economy, the new coin of the realm is learning.” Robert Reich *(cited in Von Krogh et al. 2000)*

Introduction

There is emerging attention and interests from academics and practitioners for organizational learning which addresses the promising results in organizational change and development (Kim 1993, Winfield and Kerrin 1994). With the advancement of technology such as the Internet and network communications, the endeavors of organizational learning have been transformed into E-learning activities that accentuate a wide range of electronic-driven contexts / web-based technologies to enhance the individual's skills and expertise (Burd and Dejnaronk 2000, Honey 2001). In parallel, the issue of knowledge management (KM) is referenced in business agenda that addresses the deployment of knowledge resources to sustain a firm's competitive advantages (Drucker 1995, Kougt and Zander 1992). With respect to the strategic role of information systems in the KM context, it is found that organizations undertake systematic processes in the acquisition, storage, dissemination, and creation of knowledge resources to enhance the individual's innovativeness and creativity (Alavi and Leidner 2001, Nonaka and Takeuchi 1995, Wiig 1994).

Though both notions of organizational learning and knowledge management share similar lines of thought in leveraging the individual's development and creating value to organizational intelligence, efforts to collate both notions are currently scant. Therefore, the objective of this study is to provide a starting point to address the issue of E-learning from a knowledge management perspective, specifically to embrace learning endeavors with knowledge management initiatives. Throughout the discussion, it is expected to provide a frame of reference for effective E-learning for academics to synthesize learning with knowledge management initiatives, and for business practitioners to improve the effectiveness of existing E-learning projects with the proposed KM-based aspects. Finally, the discussion will be able to inform national innovations systems theory – as the firm firmly falls in the center of innovation systems literature as the unit in which the bulk of innovation takes place in the whole system – by focusing on a key micro learning initiative at the firm level. This is important to understand the various influences that can impact a firm's level of innovativeness.

E-Learning Scope

Organizations recognize E-learning as an effective means to leverage the individual's skills and expertise that accomplish organizational goals (Lytras and Pouloudi 2001). Additionally, organizations generally concur the eclectic “e” is mainly associated with electronic means to deliver learning opportunities to their employees (Hamid 2002, Honey 2001). However, studies show that E-learning is enabled not only by the electronic medium / technology driven approaches but also other “soft” factors. For example, Hamid (2002) lists out the essential elements for effective Elearning with user acceptance towards content presentation, information architecture, interface design and deployment of learning styles. Johnson (2001) exemplifies interpersonal interaction and collaboration as the success factors that enable individuals to learn through web based communication and virtual communities. Lytras and Pouloudi (2001) allege that E-learning in higher education is more than just a learning platform using computer technology, it is a functionality of teachers, students, learning processes and technology adoption propensity.) Therefore, an examination of E-learning should not be restricted to technology driven or electronic mediated applications.

Knowledge Management Scope

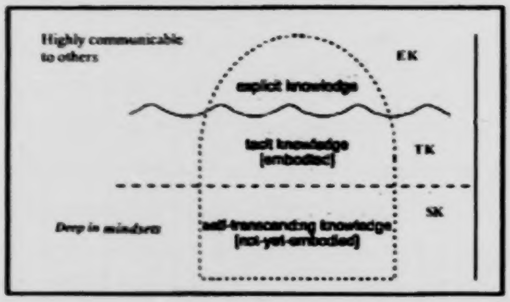
KM is contemplated as a systemic and organizational process for acquiring, storing, and communicating knowledge resources to create new capabilities for superior performance and innovation (Alavi and Leidner 1999, Grover and Davenport 2001). Contemporary surveys show that improved learning with better customer handling and decision making is a result of effective KM programs (KPMG 2000, Ruggles 1998). In particular, studies pertinent to KM best practices or prescriptive frameworks which suggest that knowledge types / taxonomy (e.g., Allee 1997, Holsapple and Joshi 1999), knowers types (e.g. Markus 2001, Pan and Scarbrough 1999) and knowledge creation processes (Nonaka and Takeuchi 1995) are crucial elements to enlarge and reconfigure knowledge repositories through justification, learning and reflection. These three elements will be discussed in the following sections.

Knowledge Management with Eclectic "E" Learning

Knowledge Types and Learning

Knowledge is discerned and widely adopted with the tacit-explicit taxonomy advocated by Polanyi (1967). The taxonomy is a multi-faceted concept and denotes knowledge as a spectrum with a fluid mixture of ideas, experience, skills and states of mind that exist inside and outside of humans (Alavi and Leidner 1999, Allee 1997, Leonard and Sensiper 1998). On one end of the spectrum, knowledge is tacit and ingrained in the human mindset e.g. personal beliefs, judgment or applied subconsciously and embodied in actions e.g. experience and skills. On the other end of the spectrum, knowledge is explicit and codified in structured and transmittable forms that can be comprehended by others e.g. words, numbers or manuals.

The three forms of knowledge, adapt and put forth the notion of tacit-explicit taxonomy suggests knowledge dynamism (Figure 1) instigated from *self-transcending knowledge* such as intuition and fragmentary memory emerge in tacit form; and externalize in explicit form through human inquiry process with justification and reflection (Scharmers 2001). Organizational learning takes place with the evolution of knowledge as individuals alert their sticky knowledge, associate among fragmentary memories, form intuitive ideas, embody in action, reflect in reality and comprehend in externalized forms. Putting knowledge types in E-learning context, "E" can mean *Exploration* that provoke extensive search of unrealized knowledge and new thoughts.



Highly communicable to others
EK
explicit knowledge
tacit knowledge [embodied]
TK
SK
Deep in mindsets
self-transcending knowledge [not-yet-embodied]

Figure 1. Three Forms of Knowledge (Source: Scharmer 2001)

Knowers Types and Learning

Knowers (or knowledge workers) are regarded as key agents who see, use, transfer and interpret knowledge, which contribute to organizational memory and creation (Davenport et al.1998, Huang et al. 2000). Knowers are alleged to demonstrate various roles in knowledge requirements, reuse applications and transfer

BEST COPY AVAILABLE

impediments that influence their learning with knowledge absorption and combination (Markus 2001, Szulanski 1996). In particular, creative problem solving is a subtle basis that influence an individual's learning inclinations and cognitive thinking in response to knowledge resources (Puccio 1999).

The creative problem solving preferences exemplify four possible styles, namely the *clarifier* who defines problems in depth; the *ideator* who stretches possible alternatives; the *developer* who puts workable solutions together; and the *implementer* who acts upon solution for realization. Organizational learning crops up during problem solving processes. Creative problem solvers who are influenced by their prevailing preferences interact with other creative problem solvers such that their knowledge and mental thoughts are amplified, compared, shared and exchanged in collective stances. Relating knower types with Elearning, "E" can be perceived as *Ego* and is the entity that provokes continual development of creativity and innovativeness.

Knowledge Creation and Learning

Knowledge creation is contented as a crucial KM endeavor to drive value-added processes where individuals deploy knowledge stored in their minds, share it within communities, produce it by discovery in new paradigms and embedded in organizational products or services (Ezingeard et al. 2000, Holsapple and Joshi 2000, McDermott 1999). Four interrelated processes – socialization, externalization, combination and internalization (Nonaka and Takeuchi 1995) – which encapsulate tacit-explicit knowledge conversion are adapted to portray learning across knowledge-creating individuals (Figure 2).

Socialization includes sharing and exchanging tacit knowledge among individuals. Typical methods of sharing are experience dissemination through apprenticeship, observation and imitation. *Externalization* involves articulating and conceptualization of tacit knowledge into an explicit form. Typical activities are induction or deduction of thoughts from dialogue, metaphors and analogies. *Combination* concentrates systemizing different bodies of explicit knowledge through sorting, adding, filtering, and combining to reconfigure the knowledge repository, e.g. integrating documents for a shared database. *Internalization* entails embodying explicit knowledge into tacit knowledge through learning and action. A typical activity is 'experimenting acquired knowledge in new problems Organizational learning results from each conversion mode where individuals engage in interpersonal interaction to acquire, elicit, combine, disseminate and implant new knowledge with their knowledge repositories. E-learning with knowledge creation can construe "E" as *Eternity* that underpins learning is undertaken at any time, in any place and by any person.

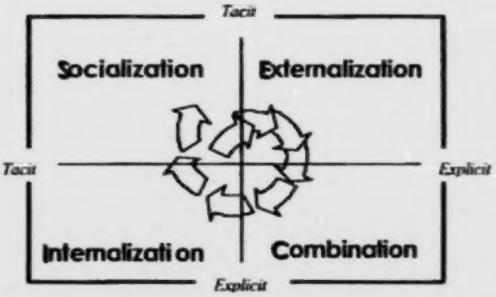


Figure 2. Four Modes of Knowledge Creation (Source: Nonaka and Takeuchi 1995)

Future Work

Based on the previous discussion, the eclectic "E" of learning is portrayed in Figure 3, which presents E-learning from a KM perspective. The discussion of Elearning from a knowledge management perspective, entailing Exploration, Ego and Eternity, is more a conceptual allegation to extend the consideration factors of E-learning than a pure technological undertaking. It is expected that future empirical work will focus on gaining a better understanding with learning endeavors to be influenced by knowledge types, knowers types and knowledge creation processes, together with the technology moderating effect in holism. This empirical work will enable light to be shed specifically on how inter-organizational alliances can be achieved so as to better a society's innovation system, and also how individual firms may adopt a variety of learning endeavors to improve the innovation system as a whole. As firms lie at the heart of any innovation system, efforts to understand learning endeavors related to institutionalizing innovative activity in a firm would be of value towards understanding any innovation system in its entirety.

An exploration of virtual community in Macau

Abstract

With the help of available technology, more channels are created to form a learning community. Although technology provides convenience to communicate, little is known about the actual utilization of it in educational settings by stakeholders such as teachers and students. This paper reports on the case of virtual learning community for teachers and students in Macau based on the observation of dialogue in online forum and the surfing of web pages. It shows that focused learning community has not been established and participation rate is still low.

Introduction

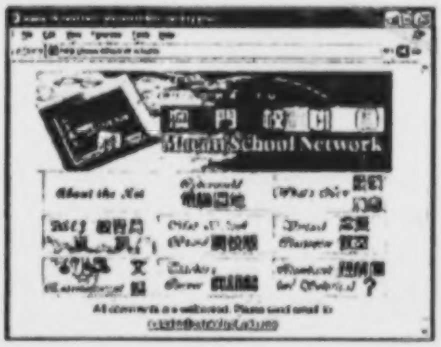
With the advent of Internet and related technology, various forms of communication platform such as discussion groups, ICQ, mailing lists, real-time interactive conferencing etc., in addition to traditional ones, are available for people to exchange their opinions and ideas. The more obvious advantages of these new ways of exchange channels for teachers are time and place flexibility. One can distribute an idea to others and gets a response in seconds at any location with Internet connection. However, it cannot be as direct as the face-to-face contact. It is even argued that the Internet allows each user an equal voice, or at least an equal right to speak (Foster, 1996). Communication barriers are reduced for people working at different levels within organizations (Sproull & Kiesler, 1996). This leads to the creation of new forms of social interactions and relations. According to Rheingold, virtual communities are defined as "the social aggregations that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace" (Rheingold, 1993, p. 5).

Virtual communities arise in both asynchronous and synchronous mode. For asynchronous community such as email lists and bulletins, participants can post messages to all other subscribers to the group that can then be responded to over a period of time. This will usually lead to the emergence of threads, or discussion topics, where a number of contributors will provide comments which support or disagree to an original posting, thus forming a dialogue of interaction. For synchronous mode, the only difference is that participants must be present in discussion. This takes place in chat room of multi user domain.

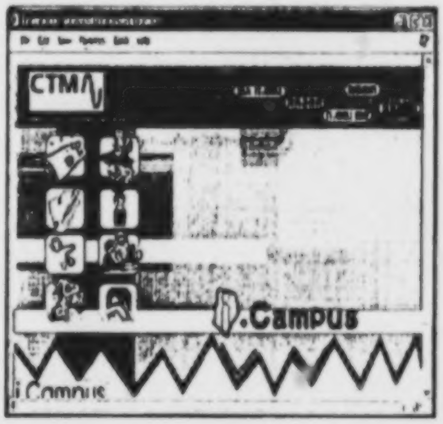
The author wants to know if there is any leaning community which focused on teaching and learning issues formed with the establishment of online environments such as web pages and discussion forum. Besides, can online environment widen the participation of teachers and students? The study will try to answer these questions by visiting web sites and discussion forum in Macau.

Overview of educational web sites in Macau

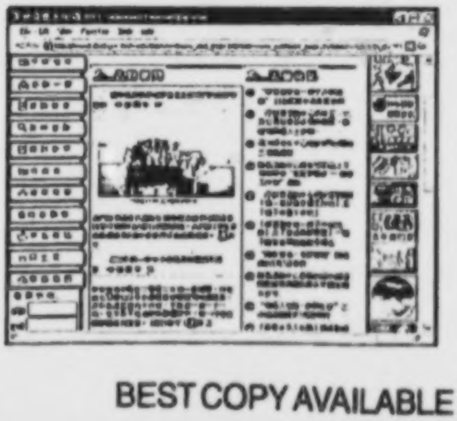
As information and communications technology (ICT) becomes more commonplace in educational settings the use of computer mediated communication between teachers is increasingly being seen as a valid form of professional dialogue and support. Macau government and other educational organizations recognize the application of ICT to promote online educational resources as virtual meeting places for teachers and students. The number of web sites in Macau is increasing each year either for public or internal use. However, most web sites for public use are for enquiry purpose. Online resources especially prepared for teachers and students are still very limited in Macau. The three major web sites are Macau School Network , i.Campus and web site of Education and Youth Affair Department . A brief description of each web site is given as follows:



Macau School Network (http://www.schoolnet.edu.mo) was first established in 1997 by a group of IT professionals and educators with sponsor from local organizations. Its goal is to form a local network for sharing resources. There are 9 sections in this web site including schools in Macau, virtual classroom, item banks and teacher's corner where teachers are encouraged to send their articles or workto the editorial board before presentingto the public.



i.Campus was a project held by a commercial company in 1999. Its aim is to promote the ICT in education. Schools are invited to join the project by having free basic equipments, Internet service and technical support. Many schools in Macau join the project as well. A web site (http://i.campus.ctm.net) for this project was launched as well. Its aim is to serve as resources center for teachers and students to use There are various sections in this web site and the most special one is a discussion forum. It allows teachers to share issues and good practice from one another



The official web site of Education and Youth Affair Department is http://ww.dsej.gov.mo It contains diversified information regarding education such as news, educational laws, educational activities, school and student statistic.

BEST COPY AVAILABLE

The three web sites described have their own features. Macau School Network web site is a place where teachers can obtain relevant academic articles and courseware At i.Campus web site, teachers can discuss with their peers and students on various topics on teaching and learning while they obtain official information about schools in Macau from the government web site. Despite the difference in the above web sites, the ultimate aim of these sites is to provide a platform for teachers, students and parents to form a virtual learning community.

Study and Finding

In order to gain a picture of virtual community for teaching and learning in Macau setting, the author collected data by visiting the web pages and participated in discussion forum mentioned in the above web sites periodically for half a year. Data was analyzed by reading the content of the topics in discussion forum dated, the number of threads posted, the number of active participants etc.

From the posting content in the discussion forum at i.Campus web site, it can be found that most participants are students with little teachers. The topic discussed is rarely concerned with learning let alone teaching. The environment becomes a place for students to express their feeling but not for discussions of lessons. The number of active participants is about ten. The level of usage is low as compared to the size of postings in general discussion forum (Burkhalter, 1999). The teacher's corner in Macau School Network web site is a place where teachers are encouraged to present their ideas. However, the number of papers available remains unchanged as compared to that at the launch of this web site. One positive fact about the usage of these educational resources is the reading rate by examining the counter provided in the web site.

The actual justification to the above situation needs an in-depth exploration by questionnaire and interview. The barriers of virtual community mentioned in Selwyn, 1999 provide a good reference to reason the above situation. There is no doubt that ICT will continue to provide significance to the learning community yet the more effort should be made to provide the community a sense of belonging and development so as to increase the coherence of the community.

Conclusion

This study shows that the atmosphere of sharing information or problems relating to teaching and learning is still quite low. A learning community, which fosters dialogue and collaboration, has not been formed yet. Sustaining virtual community is even harder. As data is collected by visiting web pages and joining the discussion, it is an indicator only. An in-depth study on the perceptions of teachers and students about web-based educational resources should be studied in future.

Learning Systems Modeling with PDA,
a Case Study

Tom S. Chan, Southern New Hampshire University

We are living in a digital age that revolutionizes the way we learn and teach. The digital world has brought forth the portable technology. Portability has a great advantage over static technology as it enables knowledge to be taken anywhere. Classrooms tend to be more interactive and collaborative. Students become more confident, creative and expressive learners. Teachers are re-energized. Work quality and quantity increases as does school attendance. Pedagogical practices also become more learner-centered (Albion, 1999).

The numbers of school where laptops are adapted in classroom are steady on the rise. For example, Massachusetts could become the first education authority in the United States to require university students to provide their own laptop computer (Olsen, 2001). Laptops imply the shift of the traditional computer lab expense to a parent-student responsibility. A laptop can be expected to cost at about 30% more than an equivalent desktop computer, and the entry-level laptop is at about $1000. Financing a laptop program is therefore, a major obstacle to its adaptation.

Released in 1996, Personal Digital Assistants (PDA) are full computers, but tiny enough to be held in the hand. Most models are approximately 3 by 4.5 by 3/4 inches. Instead of a keyboard, there's an area where a special kind of handwriting, "Graffiti," is used. In addition to this, there are four "soft" buttons for "Home," "Menu," "Calc," and "Search." Lastly, there are physical buttons for "Calendar," "Phone List," "Lists," and "Memos," plus scrolling and power buttons. Palm Organizers now enjoy the dominant position with almost 80% of the market. There are a wide range of Palms, each targeted for a slightly different audience, the cheapest and thus the most popular with 8 megabytes of RAM, can be found for about $150 (emTech, 2001).

As educational tools, PDAs are used mainly to read, write, collect, share and exchange information. However, computing requirements in the Information Technology curriculum goes beyond these general functionalities. Apart from being productivity and collaboration tools, computers are used for both systems analysis and design, and as platform for software and database systems construction (ACM, 1997). Recently, there are experimental uses of PDA as platform for database (Avanzato, Warms & Drobish, 2001) and software (Battig, 2002) systems. In this study, we are interested in the feasibility of PDA as systems modeling tools. Participants for the study are students in "Object-Oriented Systems Analysis & Design" class. This is a three-semester credits course taken during the junior year of a traditional undergraduate IT program. A significant component of the course is a term project that requires students to work collaboratively in groups to analyze and define requirements, specify design, implement, test and demonstrate a video rental system prototype; seeing the project through typical phases of a software lifecycle collaboratively as a team.

The heart of object-oriented analysis and design is the construction of a system model. A model is an abstraction of reality, constructed to understand details of the underlying problem domain. Most modeling techniques involve graphical languages or notations. Several modeling tools are wrapped under the heading of UML (Unified Modeling Language). UML is a general-purpose modeling language for specifying, visualizing, constructing and documenting the artifacts of software systems, as well as for business modeling. Models make it easier to express and communicate complex ideas. For example, an architect builds a model to communicate ideas more easily to his or her clients. During this course, the analysis and design phases require the use of Microsoft VISIO 2002, and the implementation and demonstration phases require the use of the Microsoft ACCESS 2000.

This study is currently in planning stage. Funding has been obtained for a dozen of Palm m105. Data for the study will be collected and analyzed in the fall of 2002. The course typically has an enrollment of 20 students working in four to five groups of three to four students per group. Approximately half of the randomly selected groups will be provided with PDAs. Group members are required to analyze and design their project using PDAs. In addition, they are required to complete the formal specification with UML drawings using VISIO and implement a demonstration prototype using ACCESS. All students are required to keep a weekly journal documenting their group efforts. At the end of term, a questionnaire will be collected to survey students' level of collaboration and motivation. Naturally, the quality of project prototypes will also be compared and examined.

Systems Analysis and Design (SAD) is an established area of teaching in the IT curriculum. Compared with teaching other fields, e.g., programming, SAD is notably more difficult. Creating software models is a task that requires certain level of experience. One requires not only technical skills, but also a lot of knowledge that goes beyond the technical boundaries. Practices gain such knowledge by gaining hands-on experience while dealing with problems in systems development, by interacting with users, managers and developers, and by sharing experience with others. Traditionally, SAD is taught by means of lectures, laboratory and tutorials. In lectures, instructor communicates substantial amount of information in a short time by presenting slides and explaining materials while students listen and take notes. In laboratory, students put their knowledge and skills to practice, by using CASE tools such as VISIO to model solutions to problems introduced during lectures. Outside scheduled classes, instructor also provides additional help to students experiencing difficulties.

Unfortunately, the traditional approach is quite passive and ineffective. During lectures, students listen and make very limited contribution to the discussion of presented materials. During laboratory session, students create models of more or less complicated systems given to them as assignments. There is little interaction between students and the instructor. The instructor can often only comment the effects of students' work, but not the way, which lead to the solution. Furthermore, typical computer labs with desktops are designed for lecture not conference. The rigidity physical structure impedes information sharing not only between students and instructor, and also amongst students. We often find students are not collaborated sufficiently. Instead of working on various modeling tasks together as a team, students often partition the modeling tasks to individual team member, resulting often in incoherent and disjointed system designs of inferior quality.

We need ways of involving the students into active participation in the modeling process. During such active sessions, the instructor could offer his or her guidance in applying specific modeling techniques. Students can also work and learn together as a team. Because of the portable nature of the technology, PDA should enhance active learning allowing students to engage in hands-on activity even in a lecture setting. The PDA device with an infrared beaming capability also allows students and instructor to electronically exchange software applications and data in any setting. Naturally, not all instructors will want to use their classroom as a lab, nor need they do so. A full range of teaching methods is needed in the university, and not all classes are appropriate for computer integration. In the discipline of engineering, it traditionally places great premiums on learn by doing. While PDA is convenient, the current technology cannot support specialized simulation and modeling software such as VISIO, and we are unsure of students' attitude and reaction to PDA's current graphic usability in systems modeling. Furthermore, students will have the added burden of eventually transcribing their design into formal UML drawings using VISIO.

Technology is affecting education in revolutionary ways, and the momentum toward these changes is irreversible. Universities need to become leaders in applying technology to education for learning and for collaboration. Colleges of education need to become leaders in applying computational and information technology for the K-12 community, and university administrators need to begin to chart the 21st century vision of their institutions, a journey that will include information technology and collaborative learning and teaching. Computer is important in education both for providing an employment skill and for benefiting directly the quality of instruction. The greatest single disadvantage of laptops is probably its cost as portability attracts a premium in pricing. Programs, whether mandatory or voluntary, require funding by parent and may subject families to considerable financial pressure, either increase burden of debt or deter poorer students from entering higher education (BBC, 2001). PDA as an alternative to laptop in education does warrant serious examination for it is mutually beneficial to the academic and business communities. It can provide an affordable tool for teaching and learning, and enabling the manufactures to design a user-friendly PDA interface.

Using e-learning to scaffold reflection and to support collaborative learning: A case study

Christina C. Chao
Penn State University
cchao@comcast.net

Abstract: This paper is a report on the preliminary findings of a study conducted on a graduate level student-teaching course in a large research university in the United States. Both quantitative and qualitative data analysis techniques were used to examine the resulting transcript of texts for evidence of reflection and collaborative learning within a community of learners in an e-learning environment.

Objective

The objectives of the presentations are as follows:

1) to share presenter's experience of developing a support system using e-learning approach to foster students' collaborative learning during their practice teaching experiences.
2) to share the results of the study on students' reactions of participating in computer-mediated communication in an e-learning environment.
3) to contribute the filed of online education through presenting the result of an empirical study.

Introduction

Learning is a social collaborative activity, and it occurs most effectively in context (Vygotsky, 1962). Student teachers often encounter a feeling of isolation and stress during their teaching practicum experience (D'Rozario & Wong, 1996). They were isolated from their peers and stationed in unfamiliar surroundings and had no opportunities to learn together and share their experiences. The social isolation can complicate the learning process for student teachers and thus hinder their professional development. The e-learning technologies – Internet and computer network hold great promise for extending opportunities for interaction, expression, inquiry, reflective thinking, information access, and collaboration among student teachers and thus reduce the sense of teacher isolation and also fostering learning (Reilly, 1992). E-learning environments can offer student teachers a social and learning context through which they can exchange electronic communications with each other and share their student teaching experiences.

The Study

This is a work-in-progress project. The purpose of the study is twofold. First, it examines the immediate benefits of using computer-mediated communication in e-learning by a group of elementary student teachers during their practicum experiences. Second, it examines the relationship between the goals of this computer network and the kinds of messages that student teachers exchanged. The student teachers received Internet training to perform their computer-mediated communication tasks successfully before student teaching began. They volunteered to participate in this study and they were not given requirements, and were not evaluated. The researcher was a participant-observer in the study and served the roles of network coordinator and mentor. Both quantitative and qualitative data, including student teachers' messages (mailing list postings), survey and interview data, are being collected and analyzed.

Findings

Data are being analyzed by the investigator and more detailed preliminary findings on these issues will be provided later when time comes to submit proceedings.

Conclusions

This session will benefit professionals in other application settings in the following way: The results of the study can be used to help educators who would like to use the e-learning approach to develop a support system for higher education student in general and for student teachers in teacher education programs in particular. Conclusions of the study will be provided in details later when time comes to submit proceedings.

Measuring the Digital Divide: Liberal Arts Students' IT Skills

Tracy Chao
Faculty of Arts Technologies for Learning Centre
University of Alberta
Canada
tracy.chao@ualberta.ca

Abstract: This paper reports the results from a survey on undergraduate students' information technology (IT) skill competency. The study is part of a project which is centred on the issue of the digital divide between liberal arts and non-arts students, and how that difference affects students' employability. The findings suggest that arts students are indeed behind non-arts students in terms of their IT skills and aptitude, but not uniformly or extremely. Arts students highly value IT skills and consider them important for their career. The survey results also show that arts students are as confident as others in mastering new IT skills and that formal IT training in the undergraduate curriculum is wanted.

Introduction

There is a widely held view that graduates in liberal arts are at a disadvantage upon first entering the workforce: one of the reasons being that they lack noticeable employability skills. Nowadays, Information Technology (IT) skill is becoming one of the pivotal employability skills in the workplace and liberal arts sudents seem to be the laggard when it comes to IT. The perception of an "IT skill deficiency" was documented in the Canadian National Graduates Survey "Education-Job Skills Match" (Krahn & Bowlby, 2000). The survey indicated that liberal arts graduates acquire strong writing and communication skills through their university education, but were deficient in "new technology" skills and felt their studies had not contributed very much in providing them with these critical IT skills. This viewpoint and sentiment was echoed by Robert Martin and Samuel Fee, who argued that IT skills could increase the employability and competitiveness of liberal arts students (Martin & Fee, 2002).

To further understand the issue of IT skill deficiency, Faculty of Arts at the University of Alberta conducted a survey between March and April 2002, targeted at undergraduate students' IT competencies and their attitudes toward developing IT skills during the course of their academic studies. This survey is one of the needs assessment components of a two-year project entitled "Providing a Technology Edge for Liberal Arts Students". It uses the "digital divide" as a frame of reference to contrast the discrepancies of IT skills and attitudes that may exist between arts and non-arts students. The results will form the basis for the endeavours in the development and implementation phases throughout the project.

Employability and IT skills

Many authors have written about the value of liberal arts education in the technology age and the necessity of information literacy as an integral part of liberal arts training (Breivik & Jones, 1993; Lyman, 1996; Lyman, 2001; Shapiro & Huges, 1996; Herman, 2000; Conroy, 2001). The vision of liberal arts graduates thriving in the knowledge-based economy was articulated by economist Robert Allen. He argued that liberal arts graduates have the intellectual and interpersonal abilities to cope with organizational changes and to solve problems in the rapidly changing environment brought by the revolution of information technology. Contrary to the conventional belief that an arts degree does not lead to a good job, there is evidence showing that liberal arts students do perform well in the long run (Allen, 1999). Therefore, the discussion around arts students' employability should steer away from "whether or not" arts students are employable and focus more on "what" makes them more employable.

The Technology Edge survey attempted to tackle the "what" issues along the axis of information technology competency. Several studies have made similar attempts to assess arts students' IT skills and to incorporate IT into undergraduate curriculum. Students were found to be equipped with basic skills such as word-processing, Internet, and e-mail, yet lacked the conceptual knowledge of computers and technology (McEuen, 2001). Their attitudes were generally positive and they felt confident in learning technology skills (McEuen, 2001). However, most students claimed that they do not learn IT skills through their academic studies. They learn by trial and error, and rely mostly on peer support, especially those who consider themselves computer shy (McEuen, 2001; Davis, 1999; Selwyn, 1997).

Being early adopters of IT, libraries in many colleges and universities are often involved in surveying students' IT skills and become the driving force for integrating information literacy into curriculum (Snavely & Cooper, 1997; Hepworth, 1999). Libraries' definition of information literacy is usually very broad, including practical computer skills as well as higher order abilities to think critically, to solve problems and to achieve life-long learning. Their instructional approaches range from one-time workshops to substantial on-going support (Spitzer, Eisenber, & Loew, 1998), and/or academic courses. (Urban-Lurain, 2001). However, the challenge remains in the discipline-specific integration: how to make IT relevant to the study of literature, history, drama or political science, for example.

There is little doubt that IT skills will enhance arts students' employability (Jeffcote, 1997) as IT permeates more and more into the workplace and changes the way people and organizations think and interact. Our survey builds upon the current knowledge about arts students' IT skills and attitudes, and deepens our understanding of the nature and detail of the skill sets and attitudes they possess. First of all, a comparison between arts and non-arts students is needed to determine if a digital divide exists - if so, in what shapes and forms. Secondly, how well prepared for work are arts students with regards to IT skills? Thirdly, are there differences among various arts discipline so the IT training can be tailored to be discipline relevant? Last but not least, what are the best ways to cultivate arts students IT skills during their undergraduate academic years?

Survey Methodology

Fourth year students at the University of Alberta were randomly selected to participate in the study via telephone: 408 arts students and 196 non-arts students completed it. Arts students were sampled at approximately 1:3 ratio, while non-arts students were sampled at about 1: 20 ratio. This stratified sampling allowed us to examine the differences in various arts disciplines in detail, yet have sufficient sample size to form a comparison

BEST COPY AVAILABLE

base. The arts population came from humanities, social sciences and fine arts, which are the disciplinary divisions at the University of Alberta. Non-arts students were defined as those in technology -oriented programs such as science, agriculture, engineering, or professional programs such as education, physical education and business.

Questions in the survey were designed to measure skills (an inventory of the actual skills), attitudes toward IT, and preferred ways of acquiring those IT skills. Skill inventory were further broken down into twelve categories (Table 1). Each category contained 3 to 7 questions, ranging from basic skills to more advanced, sophisticated skills pertaining to that category. For example, if students said they knew how to send and receive e-mail, they were then asked if they knew how to use an electronic address book, attach a file, and configure an e-mail program, etc. The "yes" and "no" answers to these probing questions were then coded into scores at the scale from 0 to 1 (0 being not at all competent and 1 being very competent) to reflect the skill level in that particular category.

In addition, there were three open-ended, scenario -based questions to assess students' use of IT in higher-level activities such as evaluation, teamwork and decision-making. Attitudinal measures included students' perception of the importance of the skill to their career (again recoded to the scale of 0 to 1, 0 being very negative and 1 being very positive), their IT learning experience, and their self-efficacy for skill improvement. They were also asked to identify ways and resources for them to acquire IT skills.

Survey Results

The results indicated that arts students have sufficient skills in communicating electronically, using word-processing and Internet. Their skill levels were lower on the data-related applications such as bibliographic program, spreadsheet, database and statistical program. Novel skills such as web design and conceptual understanding of how computers work seemed lacking in both populations, but the arts population was significantly lower on these skills compared to non-arts population. Overall, statistical significances were found in eight of the twelve categories between the two populations. (Table 1)

Skill categories	Arts (n=408)	Non-Arts (n=196)	X^2 P<
Basic computer tasks	S= .75	S= .85	.004
	A= .95	A= .97	n.s.

Table 1: Summary of students' IT skill and attitude by Faculty (s=skill, a=attitude, df=1, significant at the 0.05 level)

Arts and non-arts populations did not exhibit much difference when responding to the scenario questions, although arts students seemed to be more resourceful, using a mix of IT and non-IT approaches. It was obvious that the Internet (or the WWW) has become a dominant channel for seeking information. E-mail was the only IT tool students used frequently for team collaboration although majority of students still relied on face-to-face meetings since they were on campus. Discussion boards and other communication technology were not commonly used for such purpose. E-mail and other first-hand experiences (e.g. seeking advice from others, personal visits) were common when the task involves personal decision-making. Searching on the Web becomes secondary or only used as an initial entry point to find contact information.

Overall, arts students valued IT skills and thought they were important for their career. The generic skills categories, i.e. basic computer tasks, e-communication, word-processing and internet, came higher on the list, while more specialized skills categories, i.e. bibliographic program, spreadsheet, database, statistical program, graphic program and web creation were perceived to be less important. Of these specialized skill sets, interestingly, most of them exhibited statistical significance on the attitudinal measures between arts and non-arts populations. (Table 1)

Table 2 summarizes students' aptitude towards IT. Arts students scored significantly lower on all measures except self-efficacy and IT for advancing one's career.

IT skills are useful in advancing one's career	.94	.98	n.s.

Table 2: Students' aptitude towards IT by Faculty (df=1, significant at .05 level)

When questions about current methods of acquiring IT skills, arts students and non-arts students did not demonstrate much difference in their responses. The difference, however, lay in the "current methods" and "preferred methods" of acquiring IT skills. A majority of students said they currently learned IT by asking people informally or on their own. Their preferred methods were courses or work experience that would allow them to acquire the skills.

75% of arts students felt that the academic program did not provide IT skills they need for workplace: significantly higher than the 51% of non-arts students who expressed that view. In terms of the preparedness for work, 63% of arts student thought that they have sufficient IT skills entering the workplace; while 83% of non-arts students felt that way. Over 90% of arts students thought IT should be part of the academic curriculum.

We also compared three disciplines within the arts population. Not surprisingly, students were equally competent in generic skill categories. Social science students demonstrated significantly higher competency in the data-related programs and fine arts students were stronger in the graphic program. On the attitudinal measures, we found discrepancies in many categories. For example, for computer basic tasks, social science students and fine arts students showed mush more positive attitude than the humanities students. Similar pattern can be found in word-processing, bibliographic program, database, and web site creation (with different groups having the positive attitude). For data-related programs, both skill level and attitude had statistical significance. (Table 3)

Table 3: Skill and attitude comparison among three disciplines (s=skill, a=attitude, df=2, significant at .05 level)

Discussion and conclusion

The survey results drew a fairly complete picture concerning the IT skill gap between arts and non-arts students. There is no doubt that arts students were quite competent in many basic and generic IT skills. However, comparison revealed that the "digital divide" does exist: two third of the skill categories had statistical significance between the two populations. One possible explanation is that since majority of the students learned IT informally or on their own, non-arts students developed more IT skills through more exposure to IT during their studies. Our statistics further confirmed this: 58% of arts students and 68% of non-arts students reported using IT in their courses. Although we did not know how much exposure students may have outside their studies and how IT was used in those courses, we can speculate that IT in an academic environment provided students with the opportunity to learn even though they often had to resort to informal and self-directed learning. Students' preference for credited training speaks in part to the strong demand for skills development in a formal setting. However, the need for learning support in general and in close connection to academic courses is also crucial.

Arts students had significantly lower aptitude for IT, which may well stem from the assessment of their own IT competency. Nevertheless, there were some encouraging, positive results. Overall arts students thought IT is important for their career; their attitude towards each skill category was also high and always higher than their actual skill levels. That means they recognized the need for skill improvement. Most importantly, there is no difference in terms of arts and non-arts students' self-efficacy. Arts students are just as confident as non-arts students if they are to learn and master new IT skills.

The evidence supported the claim that arts students value IT skills but current academic programs did not provide sufficient training. Based on the comparison among the three disciplinary groups within arts population, we think the instructional strategies for the IT training should include:

BEST COPY AVAILABLE

(1)in-class reinforcement of generic skills that students already have: basic computer tasks, ecommunication, word-processing and Internet, (2)credited training on generic skills that students do not have but need in their career: presentation program and conceptual understanding of how computers work, (3)integration of all the generic skills into discipline-based curriculum, (4)specialized courses for discipline-specific skills: bibliographic program for humanists, statistical program for social scientists, and graphic program for artists.

This survey has confirmed that there is a digital divide between arts and non-arts students, but a simple dichotomous description would be misleading and serves no purpose in improving the educational offerings in the higher education. In fact, arts students are competent in many skill categories. The comparisons between arts and non-arts and among three arts disciplines brought more meaningful discussion to the digital divide phenomenon. It helped us not only understand the issue better but also devise well-rounded strategies to address the issue in the next phase of the Tech Edge Project.

Abstract: The purpose of this study is to investigate the impact of various computer-assisted collaborative learning environments on children's art education, as well as to further extend our understanding in this field, which previously received little attention. This proposed study should be initiated because it raises the level of awareness of the importance of collaboration in a computer-assisted learning process, and determines whether self-learning and varied collaborative learning are equally effective for young art learners. Also, it will explore whether there is an interaction between learners' prior knowledge and various types of computer-assisted collaborative learning environments.

Introduction

In the field of education, technology and teamwork have been playing an essential role in various types of educational practices, and expectedly will be continued to the next generations. It is becoming commonplace for children to learn new technologies in their young ages. Therefore, the issue of how children learn using technologies, more specifically, how they work together with technologies, is gaining much attention to investigate in current research agenda.

Many existing computer-assisted learning (CAL) systems are often used in a teacher's role in classrooms for students' individualized learning. However, opposing researchers claim that a learning process is not only from the interaction with the computer alone, but also from the interactions with companions, such as peers and tutors. In the past decades, psychologists and educators have long established the principle that children can have a powerful influence upon one another's intellectual development.

Since Smith and colleagues (1993) define the goal of art education as "to help children increase their capacities to create meaning and make sense of themselves and the world around them" (p.3), early childhood art educators are aware of being responsible for encouraging children to express themselves and to enjoy the world surrounding them. We all agree that art appreciation is essentially of an individual experience; however, the origin and the process of appreciation cannot exist outside of a social context. Based on this assumption, combining technological learning environments can offer great potential for the enhancement of collaborative aspects of children in art education (Milekic, 2000).

Therefore, the aim of this study is to investigate the effect of prior knowledge and teamwork process on individual learning achievements of art appreciation for third grade students, as well as to further extend our understanding in this field, which previously received little attention.

Research Questions

Research questions in the study include: (1) Does computer-assisted collaborative learning (CACL) benefit students' learning in art appreciation? (2) Are CACL with open discussion and problem-based discussion significantly effective in facilitating third graders' achievement in learning art appreciation? (3) Are different levels of students' prior knowledge equally effective in students' leaning achievements when they use CACL?

Literature Review

Collaborative Learning

Collaboration is an essential part of human social life. Moreover, in the classroom, collaboration is both skill necessary for the accomplishment of learning activities and a general norm to be learned. Since 1970s, collaborative learning techniques have been employed and developed successfully in classrooms worldwide at all age levels and for most major subject areas, as a strategy for improving learning achievements, such as, the development of higher order thinking/problem-solving ability (Slavin, 1996), pro-social behavior/social problems (Johnson & Johnson, 1989; Lohman & Finkelstein, 2000) and as a way to manage academic heterogeneity in classrooms with a wide range of achievement in basic skills (Bossert, 1988; Cohen, 1994).

Computers In Educational Settings

There can be no doubt that technology will increasingly be utilized in instructional environments. However, several studies have questioned whether computers would change early childhood education and whether computers can fit in the early childhood practice and facilitate young children's learning. Those studies addressed such major issues as children's development (Cuffaro, 1984; Samaras, 1996), cognitive gains (Papert, 1980; Piestrup, 1981), and social interactions with peers (Natasi, Clements & Battista, 1987).

Even though a few educators, such as Elkind (1996), claim that computers need to be used only on offering drill-and-practice activities, because a child's cognitive development cannot rely on some open-end software programs, other researchers have found that using computers with children was completed developmentally appropriate (Dublin et al., 1994; Samaras, 1996). Although the debate around the use of computers in children's constructive acquisition of knowledge is still underway, many childhood educators agree that computers can help enrich children's learning if the approaches to using computers are appropriate (Alloway, 1994; Clements & Nastasi, 1993; Haugland & Wright, 1997). Thus, computers should "support and extend children's learning, not just entertain or occupy them" (Samaras, 1996, p.133).

Learning of Young Learners

There has been extensive research on early learning that is organized as an interaction among peers. Although peer-based work is encouraged by theories in developmental psychology and classroom interventions, there are grounds for recognizing that young pupils find collaborative learning hard to sustain (Crook, 1998). Gauvain and Rogoff (1989) report that "...children as young as five years of age are not skilled at collaborating...." (p. 48). Thus Piaget's theorizing suggests that cognitive change occurs within peer interaction on one hand, but on the other hand, during the early school years, children lack the necessary socio-cognitive resources to learn effectively in collaborative arrangements (Crook, 1998). Since Brownell and Carriger (1991) commented that " As they get older, children become able to comprehend the behavior and intentions of another... Age related social and cognitive skills contributing to peer collaborations influence what and how children learn from these collaborations." (p. 381), many studies more focus on children in the upper primary grades. For example, Gillies (2000) report that positive interactions were observed among second- and third-grade students in collaborative learning.

Research Design

Participants

One hundred and twenty third-grade students will be recruited from middle/high social-economic status school district. The learning prerequisite for participants is to have capability to use basic computer tools and Internet-browsing resources.

Procedures

Pilot Study

One pilot study was conducted to test the instruction and test items before the formal study begins. The purpose of this study was to test the instruction designed by the researcher in order to gain qualitative data. Participants were required to browse the instruction individually and then take a quiz. The qualitative results observed by the researcher provide several future suggestions that include: (1) The instruction should be simple, easy to follow, and user-friendly for children; (2) Children who are under eight years old had difficulties to browse a hypertext-format instruction without learner support (such as teachers, tutors and peers); (3) Children were losing interest in about fifteen minutes.

Formal Study

The target population will first be divided into two groups (high prior knowledge and low prior knowledge) based on their previous art scores. For each group, students are randomly assigned to one control group and two other treatment groups. Before students start using the CACL, the researcher will conduct a face-to-face interview with them asking about their prior learning experiences and some other background information. The qualitative data gained in this study will be analyzed to support or question the quantitative results of the experimental study.

Conducting Experiment

The control group will work with one unit of computer-assisted art instruction individually. The treatment-1 group will be given the same computer-assisted art instruction. Instead of working individually, they will be required to work with a team of four students. Each team has two high-knowledge and two low-knowledge students. They do not have guidelines for leading their discussion on the topic to learn. The arrangement of the treament-2 group is similar to the second group, except that its participants will be given a problem to discuss. Students will be asked to complete this study in no more than forty minutes.

Assessment

After receiving the various instructional treatments, each student will be required to write down a reflective report to express her/his thoughts based upon her/his understandings on the subject matter. Two independent evaluators (art teachers) will be hired to grade students' learning performances according to the assigned standard rubrics.

Method

This study has two independent variables—different types of CACL learning strategies in learning art appreciation (open discussion versus problem-based discussion), and prior art skill (high score versus low score); and one dependent variable—outcome of students' art appreciation. As Gall, Borg, and Gall (1996) explain that a factorial experiment is "an experiment in which the researcher determines the effect of two or more independent variables (i.e., factors)—both singly and interaction with each other—on a dependent variable" (p. 508). Therefore, a two-way Analysis of Variance (ANOVA) is employed to analyze the results.

Conclusion

Collaborative learning has been widely recommended in the classroom. Understanding the potential benefits and limitations of collaborative learning from the variety of perspectives is complex, but essential. Most researchers speculate that peer learning is effective because it fosters constructive student interaction and active involvement through communication, intellectual exchange, and task-oriented cooperation. When students work on discovery-based activities, and where there are no clear solutions, it could be expected that they would demonstrate high levels of cooperative engagement. Therefore, outcomes from cooperation are more likely to include broader and deeper understandings of concepts. Based on this assumption, art is suitable for comprehension and critical discussion, and requires the learner to naturally work collaboratively. Also, computers can be superb teaching tools for a variety of art learning tasks. Especially, they are uniquely designed for delivering problem-based instruction because they lead users to interactive learning. As such, computer-assisted instruction is a potential method for small-group peer learning featuring conceptual tasks that engage in children's art learning.

Quality Management Systems for Distance Learning

Business, and commerce have widely adopted organized systems to manage quality of products and services. Terms like Total Quality Management, Continuous Quality Improvement, Six Sigma, and Baldrige are commonly accepted means of assuring adherence to quality standards. Colleges, universities and other higher education institutions have continued to rely on overall reputation and "accreditation" to convey an image or level of quality.

Distance learning and the rapid application of technology to teaching and learning processes is quickly changing the face and competition for education. Non-traditional, for-profit, and expanding programs of traditional institutions are creating global pressure on all and introducing the need for accountability and quality of outputs.

Application of ISO 9000-2000 developed by the International Organization for Standards can become a useful tool to manage the process of developing, delivering, and improving distance learning efforts. It provides a way to measure and assure appropriate leaning outcomes. This paper discussed some of the applications and implications of ISO 9000:2000 in the distance setting.

Throughout the world, it is becoming increasingly commonplace for students in undergraduate and graduate curricula to take courses and even enroll in degree programs via distance education. The competition for quality courses is increasing as higher education institutions offer broader menus of pedagogical approaches that attract students who are already in the workplace and need a flexible program to meet their career demands and schedules. This progress, however, has triggered significant issues of quality and quality management.

One college has begun to adapt and use contemporary quality tools to begin to get an indication of effectiveness and efficiency of teaching, as well as student satisfaction with distance learning initiatives. A further goal of these initiatives has been to embrace principles of quality management, and to consider quality certification under the terms of ISO-9000 of the International Standards Organization. Focus groups, comparative test results, student feedback, online surveys to measure satisfaction and inclusiveness, or community in the learning experience have been used. These tools provide a means to refine and improve on distance design, development and delivery efforts.

The targets in distance learning are quickly evolving and are fast moving; there is an ever-escalating zero-point. Customer bases are changing, and the technology advances make the effort more challenging. Yet we are trying to bring them all together for more effective learning experiences. This paper brings together the design elements, measurement activities, lessons learned and suggestions for application in the future for quality, quality management, and potential recognition through ISO 9000 certification.

Abstract

E-Learning requires students to use technologies for mediated communication and collaboration. If there are individual differences with respect to how people prefer to communicate and collaborate, then E-Learning tools and technologies should take those differences into account. In this paper we describe an inventory that we have developed for measuring communication preferences and we report on the use of that inventory in predicting newsgroup and email behaviour in a class that included an E-Learning component.

Introduction

E-Learning requires students to use technologies for mediated communication and collaboration. E-Learning tools and technologies should take individual differences with respect to how people prefer to communicate and collaborate into account. Communication preferences may be thought of as a component of personality that reflects dispositions towards performing communication tasks in certain ways, in contrast to traditional measures of personality which tend to focus on general (non-task-oriented) dispositions. Personality has been shown to have an impact on a range of human behaviours including sociability and attitudes to work and relaxation. A wide variety of personality inventories have been developed, with notable examples including the EPI, the 16PF, the MBTI and the Guilford-Zimmerman Temperament scale. In recent years progress has been made in distilling the various measures of personality into a core set of factors that seem to capture most of the variance in the basic personality distinctions. Costa and McRae (1992) have argued in particular for five stable factors of personality, which have come to be known as the Big Five factors. These factors have been labelled in a number of ways, with one set of labels leading to the mnemonic O-C-E-A-N (i.e., openness, conscientiousness, extraversion, agreeableness, and neuroticism).

Most if not all of the Big Five personality factors appear to be relevant to communication styles. For example, extraversion may be an important determinant of the degree to which a person wishes to stay in contact with others. It might be expected that certain characteristics, such as using a cell phone and interrupting meetings to take calls might be more associated with extraversion. Similarly, adhering to meeting times and emphasising schedules might be more likely associated with neuroticism.

While the Big Five personality factors should have important relationships to certain aspects of communication style it seems likely that there are other stable traits or communication preferences that are distinct from general personality factors. Our research interest is in developing behaviourally referenced measures of communication style

BEST COPY AVAILABLE

and preference. This work is motivated in particular by the increasing availability of new communication devices (such as the RIM Blackberry pager), which allow people to express their communication preferences in new ways.

Some recent studies have looked at how people communicate and interact with information technology, specifically in a virtual classroom/community and in terms of Internet use in households (Neal, 1997; Kraut, Kiesler, Mukhopadhya, Scherlis, Patterson, 1998). In a preliminary study of a well delivered and well supported distance learning class that used a variety of technologies (videoconferencing, email, internet relay chat, NetMeeting and Virtual Worlds) to mediate learning, the instructor and the students felt that they were able to create a sense of community and that they were surprised at how comfortable they felt with each other and the instructor by the end of the class (Kraut et al., 1998). It seems that given adequate support (technical, monetary and enthusiastic) community oriented communications and interactions can take place eliminating the need for face-to-face interactions and diminishing the distance barrier.

In a study that examined the use of the Internet in ordinary American households Kraut et al (1998) found that more time is spent communicating and interacting with people online via email than is spent seeking information or using the Internet for entertainment purposes. They suggest that interpersonal communication does and will continue to dominate residential use of the Internet (Kraut et al., 1998). In light of this research, Kraut et al. claim that the commercial development of Internet services and public policy initiatives to date have probably over-emphasized information and entertainment and under-emphasized interpersonal communication. Our personality influences how we communicate. Thus, investigating how personality affects our online communications and our attitudes to information technology is of particular interest in further understanding peoples' communication and interaction styles.

Based on similar motivation to understand how different people used new technologies we identified the need for a CPI (Communication Preferences Inventory) in 1999. In subsequent studies with Bell Canada and with Bell Mobility we explored relationships between communication preferences and service preferences and usage, with a focus on unified messaging and unified communications (e.g., receiving email on a phone). We then developed a draft version of the CPI that contained 24 questions (shown in Table 1). In this paper we report on a study that examined the factor structure of an initial version of the CPI, and review recent evidence of how the CPI may be a useful predictor of E-Learning behaviour.

Communication Preference Factors

A 24 item version of the CPI was placed on the Web with the questionnaire statements presented using a Likert response scale (Strongly Disagree, Disagree, Neutral, Agree, Strongly Agree). Responses to the questionnaire were then solicited from a number of people associated with the Department of Mechanical and Industrial Engineering at the University of Toronto. A total of 77 completed responses were collected. Shortly after soliciting responses to the CPI survey, we created a Web version of a short form questionnaire on the Big Five factors consisting of 44 items. Respondents were also requested to fill in this Big Five inventory. We received 40 completed responses for the Big Five questionnaire (from the set of 77 respondents who had completed the draft CPI).

In general the correlations between the CPI items and the Big Five personality factors were low, with none being greater than .5. There were however six questions that had statistically significant correlations with one or more of the Big Five factors. A factor analysis was then carried out to determine the factor structure of the questionnaire. We removed five of the six questions that had shown a relationship with the Big Five factors but kept Question 13 (which had a correlation of .316 with Neuroticism) because it dealt with scheduling which was a construct that we think is important to the CPI. Thus the factor analysis utilized 19 questions that generally had little if any relationship with the Big Five factors. The factor analysis consisted of a principal components analysis followed by Varimax rotation with Kaiser normalization (these and other analyses reported here were carried out using the SPSS statistical package). Based on a scree test, the first four factors were chosen for interpretation, with these factors accounting for 43% of the variance. The first factor was interpreted as a collaboration factor, while the second factor seemed to reflect a propensity to schedule. The third factor suggested a tendency to preview received messages. The fourth factor can be interpreted as availability (i.e., willingness to be available to take calls or communicate in various situations).

Communication Preferences in E-Learning

Based on the Communication Preference Factors uncovered using the 24-item draft version of the CPI, and a review of the literature on communication theory (Shannon, 1948; Weaver and Shannon, 1963), a 62-item revised version of the Communication Preferences Inventory (CPI) was constructed and placed on the Web with password protection. The questionnaire statements were presented using a Likert response scale (strongly disagree, disagree, neutral, agree, strongly agree). A demographics questionnaire and a personality questionnaire were also included, along with a short form 44 item (John and Srivastava, 1999) version of the Big Five personality measures (Costa and McCrae, 1992).

44 undergraduate engineering students participated in the study. In addition to filling out the questionnaires as described in the preceding paragraph, the students also participated in a class newsgroup from September to December 2001, and all messages included in the newsgroup were saved for analysis. All instructor-bound email messages from this class were also saved for analysis.

A discriminant analysis was then carried out to examine possible relationships between the CPI and email and newsgroup participation in the class. Values for communication on the newsgroup, and communication via email with the instructor, were tabulated based on those who had sent or replied to newsgroup messages or instructor emails. For each type of communication (email or newsgroup), two groups were identified: those who communicated vs. those that did not communicate. In the following discussion, numbered questionnaire items refer to the corresponding items listed in the appendix. For instance, C6 corresponds to item 6 in the appendix ("I prefer to communicate with only one person at a time"). Six items (C6, C22, C42, C44, C49 and C55) significantly (t-test, $p<.05$) between those who did and those who did not communicate via email with the instructor. Five items (C15, C25, C32, C42 and C43) significantly discriminated (t-test, $p<.05$)between those who did and those who did not communicate on the newsgroup (CPI items that differed significantly are listed in Table 1).

CPI Item	
C6	I prefer to communicate with only one person at a time.
C15	I enjoy frequenting chat rooms or engaging in instant messaging with friends over the Internet.
C22	I prefer to schedule when I will make telephone calls.
C25	I always try to keep my mobile telephone with me so I can make calls at anytime.
C32	I feel it is important for me to be able to contact fellow coworkers/students outside working/school hours for work/school related communications.
C42	I prefer to be notified of new messages immediately.
C43	I often interrupt other tasks to take telephone calls.
C44	I frequently take business/school related calls after I have retired for the evening.
C49	I feel it is important for people to be able to contact me outside of working/school hours for working/school related issues.
C55	The emotional content of my communications governs the choice of medium (i.e. telephone versus email).

Table 1. CPI significantly different between email or newsgroup users versus non-users.

These results suggest that CPI items can discriminate between relevant aspects of E-Learning behaviour. Other significant relationships were found (using stepwise regression analysis with forward entry) between CPI items (C20-C5, R^2= .207) and number of newsgroup messages sent, and between CPI items and reported number of hours spent per week on the mobile phone (C37 + C51- C29 - C52, $R^2 = 0.184$).

Discussion

The research reported in this paper shows that the CPI is relevant to the task of understanding individual differences in E-Learning. Work on the CPI is ongoing and we hope that as the research basis behind it grows it will develop into a useful tool for design and marketing. We are greatly encouraged by the preliminary evidence that the CPI has an identifiable factor structure that is well differentiated from the Big Five personality factors. Researchers who would like a copy of the latest version of the CPI should contact Mark Chignell by email (chignell@mie.utoronto.ca).

It is hoped that other researchers will also administer the CPI in their studies (and provide their results to us) as part of the process of broadening the base of respondents, leading to a standardized and normalized version of the inventory at some point in the future. We are particularly interested in studies that examine the relationship between communication preferences and E-Learning behaviour.

Acknowledgments

We would like to acknowledge the Bell University Laboratories and CITO for their support of this research. We would also like to thank Colin DeYoung for his assistance in interpreting the results, and Anna Malandrino for helping with editing of this paper.

Abstract: This paper is intended to promote further understanding about effective practices in creating fully online programs and learning environments by sharing the experiences of a faculty team which currently is responsible for converting an existing blended model into a fully online program. This presentation will address the organizational issues that facilitated and challenged the development of the first fully online degree program – the M.A. in Distributed Learning – at Royal Roads University. By October 2002, the first cohort of learners will have completed the first three courses in the program. Lessons learned from this experience are presented.

Background

Royal Roads University is a publicly funded university in the province of British Columbia that focuses on addressing the needs of the mid-career learner. All of its undergraduate and graduate programs combine short-term residency stays with more extended internet-delivered courseware. This blended model strives to ensure that educational opportunities for the working professional are accessible and flexible. Royal Roads University prides itself on achieving high graduation rates (over 90%) in all program areas. Learners also rate the programs very high in terms of quality and instructor effectiveness. Surveys and interviews with current learners and graduates confirm that the cohort-based blended learning model, with its emphasis on building an integrated and mutually-supportive learning community is a significant factor in achieving these high success and satisfaction rates.

Within this larger context, the Master of Arts Program in Distributed Learning (MADL) prepares educational professionals, training specialists, and human performance consultants to use innovative learning technologies to enhance workplace performance. MADL is an outcomes-based degree designed around a robust, program-wide competency framework. The MADL program features an initial six-week orientation, followed by a three-week residency, and then five successive terms of online coursework which culminates in the preparation of an applied thesis.

In the winter of 2002, program planners decided to create a separate fully online version of the program that would respond to the needs of potential learners who were unable to attend the three-week residency version. This variant of the program would admit its first cohort of learners in September, 2002.

This was the first experience for faculty and staff at Royal Roads University to design a fully online program in spite of the extensive collective experience in designing blended programs. There were several anticipated benefits for this initiative. First, the new program variant would meet a demonstrated demand for this format of program in an identified market. Secondly, its online format would be attractive to both domestic and international markets, and therefore, meet the university's goals for attracting international learners. Thirdly, it provided an opportunity to make linkages between North American-based learners and learners in other parts of the world. Finally, it made sense that a program that focuses on the effective use of learning technologies would be the "test case" for the development of a completely online program that might serve as an example for other programs to follow.

Facilitators, Challenges and Opportunities Within the Program Development Process

During the conversion of the face-to-face components into online courses, this design team recognized that there were critical issues that needed to be addressed in order to make the conversion process a success for learners. This brief paper presentation explores these critical issues as they pertain to the organizational dimensions related to designing and implementing an online program. These organizational dimensions are stressed in this paper because they are critical to the success of many ICT projects (Farrell, 1999).

Our experience in making the transition from a blended to a fully online model suggests that assuming that an online model is merely another learning technology for delivering courses significantly limits the opportunities for maximizing its effectiveness (Singh and Reed, 2001). We have learned that the fully online model provides a testing ground for developing and promoting new ways of learning. Reflecting on our experience with this project, there were several key organizational processes that facilitated the transformative potential of the online model. These included:

(a) *A focus on learning outcomes* – Thinking initially about the competencies that learners need to attain regardless of the program model freed the design team to consider the development of learning activities that were not necessarily based on face-to-face antecedents. The competency framework gave the design team a series of clear learning objectives that would guide course development This enabled the team to consider the design process as an opportunity to create new learning strategies beyond solely re-purposing the face-to-face activities into parallel online components.

(b) *Continuous quality improvement initiatives* – The MADL program, like all programs at Royal Roads, relies heavily on faculty and learner feedback to ensure that courses and, by extension, programs, are regularly being improved to meet learner needs. Pre-established performance goals for faculty and institutional staff reinforce the importance of delivering quality programs. This culture reinforces the importance of viewing the goal of the development of a fully online model as strengthening the program further and not just duplicating the successes of the existing blended model.

(c) *Learner-centred university philosophy* – Royal Roads University has a well-developed client-centered approach to serving learners. This is evident, not only in the design of programs, but also in the organization of critical support services such as registrarial services, IT training, IT Help Desk, and academic advising. The mandate of the university is to find ways to provide effective support to learners regardless of whether they actually reside on campus. Latchem and Hanna (2001a) suggest that this customer-focused orientation is critical to the development of organizational systems that are more responsive to the new needs of learners. At Royal Roads, this learner-centred mandate allowed the various support services to consider the development of a fully online program as an opportunity to re-think and explore alternative ways of delivering certain support services such as the creation and use of physical identification cards, learner advising, textbook distribution, and technology training. Key support services in the university viewed the MADL fully-online model as a test case for thinking creatively and differently about supporting learners.

(d) *Existing program infrastructure* – Because the blended MADL program model already featured an extensive online component, there were already elements of the program infrastructure in place that facilitated the conversion process. These included well-developed online course design models, experienced course designers, an established learning platform, and team-based course development processes.

(e) *Associate faculty model* – The majority of instructors at Royal Roads University are Associate Faculty who have a combination of academic credentials and extensive professional experience in the field. Most of the Associate Faculty are working full-time in senior leadership and consulting positions. The affiliation with Royal Roads allows them to share their experiences with learners and help them develop the necessary skills and knowledge to succeed as a distributed learning professional. As well, many Associate Faculty serve as course developers. Therefore, the Associate Faculty model provided considerable flexibility in deploying resources in order to meet the short timelines for program development.

Notwithstanding the benefits, we discovered some significant challenges and constraints that had an impact on the courseware conversion process. Major challenges included:

(a) *Limited advanced planning time* – Royal Roads exhibits many features of what Latchem and Hanna (2001b) refer to an "entrepreneurial culture" (p.33). This opportunistic, responsive, and market-driven environment, however, makes long-term course development timelines somewhat of a luxury. The fully-online program was developed in response to the demands of an emerging market made possible through a partnership with another educational provider. The importance of capitalizing on this opportunity in a timely fashion meant that the fully-online model needed to be developed within a five-month time frame. More time available would have provided us with additional opportunities to anticipate support and logistical issues.

(b) *Strong affinity for a blended model* – For a university that has based its success on blended models, the development of a fully-online program remains somewhat of a departure. Some staff, learners and faculty questioned the logic of tampering with a program model that had proven to be successful. While philosophically the university community supported the online model, operationally, there have been process challenges to be addressed. Ongoing communication has been necessary to help members of a committed learning community recognize that the fully online model exists to meet the demands of specific clientele and to provide options for selecting programs based on learner preference.

(c) *University-wide decisions that affected development processes* – In the midst of the development of the new courseware, the university instructional design team unveiled a new course development and delivery platform. This platform addressed several drawbacks of the current course management and delivery software. The timing of its release provided a short window of opportunity for the new program to adopt the platform. Its adoption, however, meant that additional time and effort under already critical timelines had to be expended in converting work that was already completed into a format readily accepted by the new platform.

(d) *Unclear global market strategy* – Latchem and Hanna (2001a) emphasize the importance of the delivery model, learning strategies, and course content respecting the cultural background of enrolled learners. Faculty made efforts in the course development process to vet the courses through representatives of specific cultural groups to ensure linguistic and cultural appropriateness. Nevertheless, the availability of an accessible, globally-offered program offering does not necessarily mean that members of these cultures will be attracted to the program unless more work need is accomplished on identifying and attracting specific strategic markets.

Summary

The creation of new learning delivery strategies should be viewed as a significant organizational change process (Singh and Reed, 2001). Therefore, by way of summary, here are some key organizational issues that we have considered so far in transitioning from a blended or face-to-face model to a fully online model. We have framed these as questions for readers considering this conversion process:

1. Have you considered the needs of the specific learners you are attempting to serve with the online program? What evidence exists that your online model will meet their needs and expectations? If international learners are being recruited, how is your online program responding to their cultural needs?

2. Have you assessed the institutional impact of developing a fully-online program? Will processes and systems need to be created, changed or re-developed to address the needs of a fully online learner?

3. Do you have an opportunity to develop a pilot process with a smaller cohort of learners to test out the delivery of the online model? Will this process help you address critically short timelines for development and implementation?

4. Are you committed to viewing the development process as a means of discovering and developing new ways of learning? What kinds of supports exist to ensure that this happens?

5. Are your learners prepared for a fully-online learning environment? What supports need to be built into the program to maximize opportunities for their success? Is an orientation to the online learning program necessary to ensure that learners are sufficiently ready to make the transition to an online learning environment.

6. What kinds of evaluation and feedback measures will you put in place to enable ongoing modifications to be made to the program?

7. What kind of professional development is in place to help support faculty and staff fully exploit the opportunities of creating a fully online learning model?

8. Are faculty and program support personnel clearly aware of their roles in supporting student learning in an online environment and how these roles might be different fom those in more traditional learning environments?

Abstract: This system of music instruction focus on using technology to enhance secondary general music education. Features include how technology allows students to learn at their own pace and to do musical group performances that leverages on technology.

Introduction

In Chung Cheng High (Main) School, technology is harnessed for music education to promote the belief that everyone can eventually learn to play music from any level of competency. A programme has been created to generate synergy between general music education and niche education for secondary school students. A niche co-curricular activity was first started in 2000 to nurture students interested in both IT and music. The niche programme creates opportunities for students with music background, to explore the use of IT for music arrangement and performance. Subsequently, IT music was introduced in the general music programme a year later, in 2001, where *secondary 2 (K 10 equivalent)* students learned how to play the electronic keyboard through gaming and this made the learning of instrumental playing more exciting. Partnerships were also established to help develop the programmes, train teachers from other schools and provide infrastructure maintenance and support.

The focus of this briefpaper will be on the design, development, implementation and review of the *Instrumental-playing Module*[1] of the general music programme from 2001-2002.

Motivation and Opportunities

The entire project was motivated by the desire firstly to provide all students, regardless of family financial background, with an opportunity to learn to play the piano keyboard and secondly, to identify talents from there.

In 1999, with the support of the cluster schools' funds, 10 computers were purchased to start niche IT music club with a pilot group of students interested in both music and IT.

When *BlasterkeyMP3*[2] was introduced in 2000, there was the possibility of harnessing the new hardware and software to enable 40 students to learn some basic keyboard skills at their own pace and time almost simultaneously. Another budget was sought and granted to purchase the additional 12 computers together with the 22 sets of newly invented equipment on a promotion price of half the normal price. Together with a fellow music teacher, Ms Ng Chuen Yin, the *Instrumental-playing Module* was resttuctured to harness the new technology for learning.

General Music Programme (Instrumental Playing Module)

The restructured *Instrumental Playing Module* was introduced to the Secondary 2 in Terms 3 and 4 of 2001. The focus of the programme shifted from recorder playing to learning to play the midi-keyboard using 22 computer music workstations for a typical class-size of 40. It was a breakthrough achievement when all students could simultaneously learn to play the keyboard on their own, while the teacher could move around to give pointers with regards to choice of pieces and hand-posture.

---

[1] A module of music lessons lasting one semester which is approximately 16 weeks.

[2] A product of Creative Technologies consisting of several software and a midi keyboard controller that can be linked through a game port.

Instructional design for IT Music Lessons

Table 1 below is the scheme of work for the Instrumental Playing Module with technology incorporated to enable and encouraged learner-centred and self-directed learning.

Week	*Lesson/Objectives*	*Activities*	*Resources/Assignments*
1	Blasterkeymp3	Lesson 1 and 2. Those with music background will help classmates. Pairing wok needs to be done. Teacher to assign students to specific workstation.	Computers, Blasterkey, BlasterkeyMP3 software, projector.
2-3	Blasterkeymp3	Lesson 2 and 3. According to pupil's ability.	As above.
4	Rhythmania	Introduction to chords insertions.	Computers, Rhythmania, any music sheet with chords, pupil's diskette.
5	Rhythmania	Introduction to different musical styles.	As above.
6	Issue and clarify performance assignment	Students are to perform on instruments of their choice in groups of 4-5 with a simple sequence of any music arranged by them.	Computers, software, music scores. Assignment handouts.
7-9	Sequencing or rehearsals	Students will bring their scores to sequence or rehearse their performance. (Some students might need to work on their competency with at least one instrument.)	Computers, software, music scores.
10	Buffer Lesson	Some classes may not have this lesson as it might be accounted for by public holidays.	
11	Rehearsal Week	Students are free to ask teachers for advice to further improve their performance.	
12-15	Assignment Presentations	Students will present the performance to the class in their groups.	
16	Post- Assessment Review	Show students video of some excellent examples of the assignment.	Projector, computer.

Table 1: Scheme of work for the Secondary Two Instrumental Module

For the first six weeks, two software i.e. the BlasterkeyMP3 and Rhythmania, were introduced and were to be used throughout the rest of the module:

1. The BlasterkeyMP3 software was introduced to allow the students to learn the keyboard at their own pace. Lessons 1, 2 and 3 of the programme were used. The following is a brief description on each lesson.

- Lesson 1 introduces the piece, students are asked to listen to the tune.
- Lesson 2 guides the students to play the notes of the piece using interactive pointers pointing to the respective keys on the keyboard, with no time or rhythm constraint.
- Lesson 3 requires the students to play in real time. Students may choose from many short pieces of various levels of difficulties to learn. The tempo for each piece may also be altered to suit the ability of each pupil.

The number of pieces are not exhaustive, since new pieces can be also created by the teachers and uploaded into the programme. The gaming feature in the software programme is interesting and fun. It feedbacks the results to the students immediately with both a percentage score as well as with cheers and applause. Thus the students are motivated to try to play better each time.

BEST COPY AVAILABLE

2. The second programme, Rhythmania, is an auto-accompaniment software, which allows the students to create their own sequence to accompany their instrumental playing without much music theory background required. This greatly enhances their instrumental performance experience from playing on their own often in unison to playing with music accompaniment generated from the computers. This also allowed them to practiced individually with the midi-sequences at home and reduces the amount of time needed to rehearse the performance together as the midi-sequence also acts as a kind of metronome that keeps them playing together when they meet. Many students have since created interesting sequences to accompany their recorder or keyboard playing.

Music Assignment Presentation in 2001

Students were required to complete an assignment for the Module. They were to work in groups to perform a piece of music of their choice, given the following guidelines:

- Each group should consist of 3 to 5 members
- Only instrumental performances are allowed.
- The use of either midi arrangement by members of the group is necessary.
- All members of the group are required to give a "live" performance.

The assignment encourages both student collaboration as well as independent learning. Students are engaged in choosing the own piece of music, as well as making decisions with regard to the style and the instrumentation of the music arrangement. They were also given rehearsal time during class lessons, where they can consult the teacher. Through the process of working on these assignments, motivated students were also introduced to other skills, such as MIDI sequencing and editing which helped to enhance their assignments.

As many students do not have the necessary IT equipments and software at home, the music lab was made accessible to them after school two weeks prior to their presentation for groups that were unable to complete their work during lessons. The music laboratory was manned by IT Music Club students. The students were very enthusiastic about the assignment and many stayed back till late afternoon to either rehearse in their groups or practice their individual parts. Many students with no prior keyboard playing knowledge were able to perform simple parts in their groups. Many groups also created sequences to accompany their performances. The assignment was assessed to Techniques (30%), Rhythm (30%), and Expression (40%).

Review and Improvements made in 2002

For 2002, the scheme of work was revised such that students will have sufficient time to complete their assignment during their normal lessons and few will have to stay back late to rehearse or sequence their performance.

The assessment criterion has been revised to include Music Arrangement (20%), Group Rapport (20%), Introduction to performance (10%), Stage Presence (10%) in addition to Techniques (20%) and Expression (20%). Table 2 below shows the summary of improvements made to the programme for 2002.

	2001 Areas for improvements	**2002 Improvements implemented**
1	Students take the soft option to play unpitched percussion.	Students have to play melodic instruments with the exception of one drummer per group.
2	Sequencing is optional, thus some arrangements without sequences would sound inferior to those that have.	Sequencing is made compulsory and achievable.
3	Experimental rubric was designed and used.	An improved version of rubric is used to achieve desired learning outcomes.

Table 2: Summary of improvements for the 2002 Instrumental Playing Module

Conclusion

The general music programme of Chung Cheng High (Main) School with its leverage on technology has been increasingly recognized as a leader of its kind in Singapore together with its other programme for specialized individual students who will continue to explore modern technology for music-making and education. It has opened many new possibilities in terms of how technology can be further integrated in the learning of music and musical instruments and will likely provide inspirations for new innovations in the education of manyother disciplines.

Web screen design: background color impacts posttest performance

Abstract

This investigation considered the effects of background color in an online vocabulary lesson. In real-world settings, background color used on the lesson screen may not be available when the lesson content must be recalled. Equivalent posttests were designed with or without matching color. Results show different posttest performance when matching color is present at posttest versus when it is not. Results indicate that background color serves more than just a decorative function in screen design.

This investigation considers the effects of background screen color as an over-arching context variable when learning from computer displays. Background color scheme may be only decorative, but sometimes indicates related sections of the web site (Voithofer, 1997). This approach follows from print-based design. However, Misanchuk (1992) says, "This kind of color coding is done on the presumption that it helps orient learners to the tasks at hand, but apparently no research has actually been done regarding its effectiveness for that purpose." (p115).

Dwyer and Lamberski (1982-83) in a review of the effects of color in teaching and learning have reported that color that is used to explicitly associate related content is more effective than not including color, especially for recall learning outcomes (a drawing task), though sometimes color is not more effective, especially for recognition outcomes (Worley & Moore, 2001). Similarly, Winn and Everett (1979) have concluded that when color draws attention to important lesson content, this improves recall of both the important and also irrelevant lesson information (Pett & Wilson, 1996). Dwyer (1978) summarizes the likely encoding effects of color when he says, "...color facilitates information processing by providing structures for the storage of new information and by providing categories by which familiar or already existing information can be more efficiently stored." (p.142)

The present investigation, motivated by the current use of background color in web sites, considers the effects of screen colors across a web site, which would involve associating multiple disparate propositions across many screens, rather than just a few related propositions within only one or a few screens. In this case, the instructional efficacy of color is not as clear (Pett & Wilson, 1996).

In many real-world tasks, the color provided at encoding may not be available at retrieval. Transfer appropriate processing (TAP; Bransford & Franks, 1976; Morris, Bransford, & Franks, 1977) proposes that lesson and retrieval processes should correspond. Thus the use of background color in a lesson may have a negative effect, since the encoding task has color and the retrieval task does not. Such a finding would have serious negative implications for this use of color in screen design. Thus, this investigation examines the effects of the presence or absence of screen color at posttest.

Method

Participants

The participants (N = 34) in this investigation were graduate students. About 78% of the participants are full time employees of local corporations and businesses, and 20% are school teachers; most were female (75%) and all but one are in their late-twenties. (Note: we are adding more participants by November 2002).

Materials

The study task provided the 36 common instructional design terms in multiple-choice format with one term per screen. Knowledge of correct response feedback was provided. The 36 terms were arranged in the order of their occurrence in the introductory instructional design textbook (Dick & Carey, 1996), and were divided into five groups each assigned a color. These groups include: Overview (orange) – items 1 through 9, Instructional Analysis (yellow) – items 10 through 16, Learner Analysis (blue) – items 17 through 22, Objectives and Tests (green) – items 23 through 27, and Development and Evaluation (purple) – items 28 through 36. These color hues are not normally associated with these terms or groups (such as using red to indicate a concept such as "stop"). The color associated with each group was designed to appear as merely decorative. The color was displayed on the screen as a solid column 1.4 inches wide along the left margin.

Posttest

The posttest was designed either with no color, or with color that exactly matched the lesson items. The posttest consisted of the same 36 definitions as before, except that the first 18 items were constructed response format while the second 18 were multiple-choice format. The posttest was partitioned into 9 "easy" and 9 "difficult" items, thus the 36-item posttest has four sections including constructed response with easy items (9), constructed response with difficult items (9), multiple-choice with easy items (9), and multiple-choice with difficult items (9).

Results

Posttest data (see Table 1) were analyzed by 2 (Test Context, color or no color) X 2 (Test Format, constructed-response and multiple-choice) X 2 (Difficulty, Easy and Difficult) mixed ANOVA; the first a between-subjects variable, and the second two, within-subjects variables.

Table 1.
Means and Standard deviations.

Posttest		CR		MC	
	Lesson	difficult	easy	difficult	easy
Color	28.8	4.8	5.6	6.6	7.5
n=17		(2.1)	(2.2)	(1.4)	(1.2)
No color	29.0	4.0	5.9	7.5	8.1
n=17		(2.3)	(1.7)	(1.2)	(1.0)

Four significant findings were observed. The repeated measure Format (CR and MC) was significant, $F(1, 32) = 72.497$, $MSe = 2.500$, $p < .001$, MC scores were greater than CR scores. The repeated measure Difficulty (easy and difficult) was significant, $F(1, 32) = 72.363$, $MSe = 1.432$, $p < .001$, with easy greater than difficult. The interaction of Format and Difficulty, $F(1, 32) = 4.224$, $MSe = 0.921$, $p = .048$, and the 3-way interaction of Context (color or no color), Format, and Difficulty, $F(1, 32) = 4.224$, $MSe = 0.921$, $p = .048$ were both significant. Follow-up analysis of this complex interaction compared color to no color for MC easy, MC difficult, CR easy, and CR difficult posttest subsections. A significant difference was only observed for MC difficult posttest, with the no color mean ($M = 7.5$) greater than the color mean ($M = 6.6$).

Discussion

This investigation considered the cognitive and instructional effects of background screen color. Color impacts posttest performance. Including matching color during posttest reduced multiple-choice posttest performance for TBR content relative to the no-color posttest and improved constructed-response posttest performance for TBR content for difficult items.

Pett and Wilson (1996) note that color is often used by instructional designers without due consideration for what is already known. The use of color in screen (and print) design is common practice, yet much empirical and theoretical work remains to be done in order to guide our practice.

E-LEARNING AS TELEWORKING TRAINING TOOL

Abstract: This paper describes how it is possible, with the help of innovations in systems and data processing, and relying on more efficient means of communications, performs several work activities outside the traditional office.

Hereby, characteristics of a teleworker profile, skills, and any issue related to success on applying Teleworking will be explained in detail.

E-learning comes to be an essential tool for teleworkers. This new methodology of training has to be incorporated in the organizations who adopt Telworking. Now, flexibility takes a key place in the organization goals.

E-learning as distance training will provide new opportunities to employees and benefits for companies.

Introduction

As a result of multimedia and internet fast expansion a new modality of work appears: *Teleworking* also called *Telecommuting* or long-distance work.

Teleworking is a set of technologies that complement and extend the dynamic ways of work. It is not only work at home instead at the office, it is about to take the office where the worker is (Ryan, 2000). What it matters is what it is done, when it is done and not where the work is done.

E-learning is the key for companies to constantly keep their employees trained in a world where technology advances day by day.

The advantages that distance education presents for teleworkers are even better than the employees who work at office are, because they need this type of training owing to be located in decentralized form.

For employees, Teleworking and distance education (or distance learning) improve life quality, eliminating transfer times which overload with pollution the environment and for the company it brings an enormous amount of benefits.

Terminologies

A vast terminology in the field of Teleworking and Elearning does exist. Now, it will be explained the most common terms:

Telecommuting - Teleworking - Teletrabalho: it is the process to take work to employees instead of taking them to work. The activities can be made outside the company eliminating the obligation to travel to the corporative office.

Telecommuting is the term used in the United States to designate Teleworking. The english word *commuting* means "go to and return from house to work". In Europe the term used for this modality of work is Teleworking and from there the translation to Teletrabalho in portuguese (Mello, 1999).

Home Office: the work place is in the employee's house.

Virtual Office: they are also known as Business Center. These places give services to professionals as Entrepreneurs or Teleworkers. There, is provided and offer everything what it is needed for work: telephone, computer, fax, account assistant, etc (Mello, 1999).

E-learning - Distance Learning. , it is a general term used to cover the broad range of teaching and learning events in which the student is separated (at a distance) from the instructor, or other fellow learners.

Distance education: "the process of extending learning, or delivering instructional resource-sharing opportunities, to locations away from a classroom, building or site, to another classroom, building or site by using video, audio, computer, multimedia communications, or some combination of these with other traditional delivery methods. (ITC, 2002)

Two things are necessary to start with Teleworking. In accordance with Nilles (1997) the first thing to do is mount a domestic office and structuralize a good environment of work. Second, it is essential to act with good sense and reprogram the mind in order to have success in this new labor situation.

Teleworker and Telemanager profiles

According to Talia Besga (Besga, 2000), Teleworking it is not suitable for all work stations nor all employees of the organizations.

One of the most important problems of teleworkers is isolation, both in working tasks as training. The person is alone in front of the computer without having face-to-face contact with colleagues, manager, boss or professor. Moreover, it is exposed to any kind of distractions like: neighbors, children, friends, TV, etc. Consequently, teleworkers have to have an adequate psychological profile for succeed.

Telemanagers (managers supervising teleworkers) or tutors, also do need to have a suitable profile, not all managers or supervisors are apt to *telemanagement*.

Teleworker profile

To be efficient in this context it is necessary to have some characteristics that will be fundamental for a good performance in the loneliness of the house.

Ideal teleworkers must combine the following aptitudes:

- Auto-motivated
- Auto-disciplined
- Capable of work with minimum supervision
- Organized
- Good communicator
- Not addict to work
- Well-disposed to participate in meetings and courses
- Professional Experience in working area (min. 3 years)

Making a test of aptitude facilitates enormously take a decision to name the right candidate to telework.

Telemanager profile

Teleworking forces managers to be better. The telemanagers role has emphasis in leadership and not only in administrative and control tasks.

Therefore, telemanagers will be questioned and required with much more incisive form by employees. It must be remembered that virtual environment levels up hierarchic relationships.

Most important skills that a telemanager must have are: positive attitude in relation with Teleworking, manage by measuring results, delegate assignments among telecommuter, organized, opened to receive new ideas, trust in teleworkers, communicative, etc.

Managers who are best at handling teleworkers and other remote employees tend to be good at scheduling and managing work assignments and identifying workflow problems before they turn critical

Training using E-learning

Teleworker training can be divided in two groups:

- *Teleworking Training:* it is necessary to be a good teleworker (technological tools, motivation, tips, etc)
- *E-learning Training:* the employee needs to acquire new knowledge (abilities for work)

Employees have to be always studying new technologies and trends (specially have basic & advance knowledge in computer and telecommunications). Therefore distance education is perfect for training today's teleworkers.

Training evaluation

Training evaluation could be:

- *Formative*: this type of evaluation is made along the course through auto-evaluation tests or with tutor monitoring.
- *Summative*: final exams or intermediate works are used to evaluate. Generally it required employee presence to guarantee credibility of the process and may be obtain a certificate or diploma.

Normally, in organizations that use E-learning to train their employees, the summative evaluation not exist, since it will be made a "real test" evaluation when abilities acquired have to be implemented during the exercise of the profession.

E-learning system evaluation

The E-learning system must be also evaluated. Evaluate the model, the technologies, the organization where it will be apply to, the type of evaluation offer, the attendance, the services, the duration, the action plan, the interaction systems and management processes.

To evaluate distance learning software executed via internet, it has to take into account the following characteristics:

- Have e-mail, forum, chat and discussion lists
- Automatic generation of reminders to concerning tasks and deadlines
- Automatic generation of statisticians concerning: employee access in the different modules of the course, accomplishment, bulletin boards of tasks, employee evaluations and participation level in group lists, forums, etc.
- Easy visualization of reminders, calendar and bulletin boards
- Easy access to obligatory materials and essential information
- Easy way to send the tutor tasks and evaluations
- Permit access to authorized users, giving password to guarantees the access to all materials and activities

Advantages introducing E-learning

Advantages for the company

Advantages obtained when introducing E-learning in an organization are:

- Allow training without the necessity of leave the place of work to attend presence courses
- Possibility to train a bigger amount of employees more quickly
- Required time to distribute information into the organization can be reduced to few hours
- Can be used as a tool for management of knowledge: it allows in such a way to identify profiles of abilities of employees and of its work stations

Advantages for the employee

Advantages that *E-learning* offer to normal employees and teleworkers are:

- Possibility to learn at any time
- Information is always available, therefore it is not necessary to take days nor hourly fixtures for training
- Contents that already are known or are not needed can be passed quickly while spending more time in those contents that are considered important

Conclusions

Of course, organizations have changes as consequence of Teleworking, it comes to bring more freedom and flexibility to the companies and employees.

Organizations will be able to work in a geographic decentralized way (distributed organization) and have economic, social and cultural improvements. Moreover, the advantages will be transferred to employees and managers.

In a competitive world, speed and autonomy play an important role, so E-learning is the key to get teleworkers trained in state-of-the-art. Today, it is demanded more and more expert and qualify professional so distance learning comes to help in the evolution of this process. Distance learning schedules, education formation modules, access to new technological tools, possibilities to be formed during working hours are vital items nowadays to be present in a competitive market.

E-learning does not embrace only employee's formation; it must be extended to all value chain: managers, suppliers, customers. They all should collaborate in make this new project work, it would be important they contribute and be informed about contents, changes, updates information, etc.

Finally, an implementation of an E-learning platform will be, undoubtedly, the future in training field in the organizations.

Using Virtual Poster Sessions in a Distance Education Course

Patrice Clemson, Pennsylvania State University

ABSTRACT

The poster session is a form of scholarly communication used in many disciplines to present early research findings and works in progress, The poster is easily adapted to the World Wide Web, offering the ability to collect related presentations from researchers at geographically dispersed locations. This presentation will explore the planning and implementation of the poster site developed for a graduate distance education course. Students in the course develop information products for their final project and make 10-minute presentations of the product prototype. Responding to requests for access to current and previous presentations, this instructor has organized these class presentations as virtual poster sessions. The medium provides an electronic publication opportunity for the student during the course and after it has ended. Students have immediate access to their own work to share with colleagues and enhance their own portfolios.

INTRODUCTION

The advent of the World Wide Web has accelerated innovation in the delivery of distance education at all levels. Faculty are developing new teaching methods for this new medium, the likes of which would not be possible before. Instructors are also converting established educational methods into their Web-delivered equivalents.

This paper describes the virtual poster session and permanent collection of final projects in a Masters level course delivered through the University of Illinois Graduate School of Library and Information Science LEEP (Library Education Experimental Program) distance learning program. Over the past few years there have been students in this class from Alaska, California, Oklahoma, New York, Georgia, Mexico, Missouri, Illinois and many other locations. There are also some instructors who live outside of Illinois. Students begin their course of study with a "boot camp" where they are introduced to the synchronous classroom environment, HTML and some of the other tools they use during the term. Then the students and instructors meet on campus for one weekend every term. This is a graduate professional program designed for educating students who are geographically dispersed.

The paper will review the evolution of the idea over several academic terms, present examples of the poster session and permanent collection formats, and explore enhancements that are possible with these media in this educational environment.

ASPECTS OF THE PAPER

There is a strong tradition of the poster session as a form of scholarly communication. Many professional groups, in the sciences and health care, schedule poster sessions at their conferences and meetings. The poster session is especially significant in the library and information sciences. The American Library Association (ALA) and American Society for Information Sciences and Technology (ASIST) hold extensive poster sessions at their annual meetings. This is evidenced by the fact that ALA publishes guidelines for the preparation of posters. This significance is also reflected by ASIST conference scheduling their poster sessions so as not to conflict with other conference events.

The final project presentation exercise in the LIS 315: Network Information Systems course exhibits many of the features of the poster session. The course's final project assignment requires that each student develop an information product related to networking or library automation. The final project presentations are delivered at a scheduled time and place. There is a 10 minute time limit for the presentation, so the content and supporting materials must be concise. Class chat rooms provide colleagues with the opportunity to interact with the author and ask questions. Finally, each presentation has a Web page component to provide print, audio and visual support to the student's discussion.

There are some improvements that could be made to the class sessions where the presentations are made. Time limits must be imposed so that ten presentations may be made within a two-hour class meeting. Additional chat room meetings could be scheduled to allow the presenters to field questions about their posters. Alternately, discussion lists could be set up for the purpose of exchanging ideas.

Another aspect of this paper on virtual poster sessions deals with the preservation of the posters in a permanent Web-based collection. Because the interactive poster sessions are conducted during regular class meetings at the end of an academic term, there are problems with accessing the project materials after the term has ended. It has become desirable to store many of the posters in a stable place.

Some issues related to virtual poster sessions and permanent storage of the presentations in the context of a Master's level distance education course focus on the protection of the student's privacy and intellectual property. Because the project presentations are part of a regular academic course they reside on the GSLIS LEEP server and are accessible by authorized users via user ID and password. Furthermore, all project materials are stored together with others presented on the same date. The LEEP server directory architecture is reconfigured each term. At the end of the course, materials for the permanent collection must be identified and moved to another location on the secure server. Before this is done it is necessary to obtain each student's permission to add his or her poster to the collection. Once permission has been granted there are issues relating to maintaining and updating the Web site. These are technical issues of information architecture, metadata and classification of the web pages.

Future enhancements to the permanent collection are being considered that would enable communication between the audience and the authors of the posters. It may be possible to establish a monitored bulletin board on the Web site or electronic mail links to each author.

CONTEXT AND MOTIVATION

The poster session is perceived as an important vehicle for scholarly communication in many professions and disciplines. This provides ample justification for learning and practicing the use of this medium during the course of graduate studies.

Final project presentations in the Network Information Systems course follow a general format that is quite similar to that of a poster session. With several minor changes this assignment can be enhanced to provide the graduate students with practical experience with a communications form they are likely to use during their professional careers.

During the two years this course has been offered this instructor has received continuing requests from students for access to prior term projects. Once students reviewed previous projects' content and form many of them remark that they understand what is expected. Having the opportunity to see what others have done is often a catalyst for our own creativity. The "poster session" website was implemented on the LEEP server to guarantee that the site and its contents will be accessible only by LEEP students, faculty and staff.

The permanent collection was intended to provide a stable location for student work so it would continue to be available after the course had ended. A student might like to include the project in a portfolio or otherwise share the work with a potential employer. Several student projects were actually part of larger projects. The collection was designed to allow one to revisit the work as it existed at a particular point in time.

This body of project work reflects the intelligence, creativity and hard work of a group of highly motivated individuals. In the past, many of these projects were effectively finished once the presentation had been delivered to the class. This instructor and the students now have the means to share the wealth of creative projects with their colleagues.

AMEE: Annotated, Multi-modal Electronic Evaluation for Dynamic Student Modeling

John W. Coffey and Michael Webb
The Institute for Human and Machine Cognition
The University of West Florida
Pensacola FL 32514

Abstract: This paper contains a description of AMEE – Annotated, Multi-modal, Electronic Evaluation system. AMEE provides capabilities to create evaluation tasks (including tests) that contain annotations indicating the topic areas and dimensions that the task addresses. AMEE is multi-modal in the sense that the student can answer questions that require point and click (true-false or multiple choice questions), keyed essays, or drawing (pictorial answers, solving math problems by hand), etc. The scored results of the evaluation items can be assembled into a visual representation of a student progress model that can be used by the student and instructor.

Introduction

In this work we describe an evaluation tool that is designed to serve the creation and maintenance of a student learning model. The components described here are part of a content recommender subsystem that in turn is part of LEO, a Learning Environment Organizer (Coffey, 2000; Coffey and Cañas, 2001) based upon Assimilation Theory (Ausubel et al. 1978). This work takes its impetus from a variety of research areas including electronic testing and user modeling, and an ontological account of a learning system (Coffey, 2002). The remainder of this paper contains a brief description of relevant literature on electronic testing and student modeling, AMEE's testing component, and the contents and visual representation of the student model provided by the system.

Related Literature

With the proliferation of computers and distance learning, electronic testing is gaining much more widespread use. Kirka and Wonacott (2000) describe benefits of electronic testing such as the ability to carry out continuous assessment of a variety of types. They cite drawbacks such as security issues, the impersonality of computerized testing, uneven access to technology, and potential technical problems such as connections going down in mid-test. Another problematic issue is the fairness of electronic tests. Mason, Patry and Berstein (2001) concluded that computer-based testing led to similar outcomes to those that were attained through traditional testing approaches. On the other hand, Wingenbach (2000) concluded that students taking pencil and paper tests scored significantly higher than the group that took electronic versions of the tests.

Researchers have explored and refined methods of creating and maintaining computer user models for decades (Rich, 1979; Finin, 1989). Bull, Brna and Pain (1995) state that each instance of a student model must be domain-specific within the educational context, and must include a characterization of student performance in the domain, sequencing issues, the use of analogy, the employment of varying learning strategies and metacognitive issues such as awareness and reflection. Shute (1995) describes SMART, which models knowledge and skills in a manner that includes diagnostic information, such as the level of assistance the student required on a topic, and remediation information.

Cumming (1991) discusses Intelligent Educational Systems (IES) that provide comments and advice with the student in the role of collaborator rather than the role of someone to be led by the system. A collaborative IES is congruent with current educational theory that emphasizes increased learner control (see, e.g., Lawless and Brown, 1997; Schweir, 1995). Kay (2001) states that, in the broadest sense, the goal of user modeling is to create a representation that indicates user cognition and performance. The quality of a user model lies in the fidelity with which the model represents the actual state of the human. With AMEE, the topic of this work, a student model contains a variety of information including progress information on courses and topics completed and student attainment levels expressed in terms of:

- Areas of study – intuitively, the topics in a course, and
- Dimensions of competence – orthogonal to areas, these are measures of capability within an area.

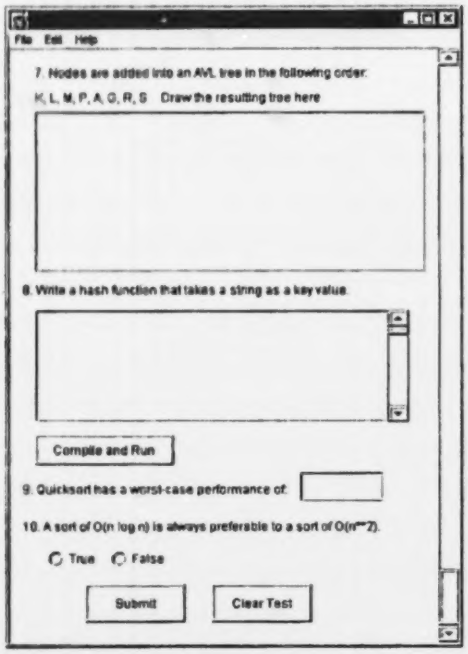
The areas or topics may be in any of four states – completed, current topic, ready or not ready. The names and number of dimensions is domain-specific. Area and dimension descriptions are used to annotate questions.

Annotated Multimodal Electronic Evaluation and User Modeling

AMEE provides an environment in which instructors can create annotated tests and other evaluation vehicles. The evaluation items are annotated with descriptors that can be used to provide a high-resolution representation of student achievement in terms of the areas and dimensions that comprise a course. The evaluation items are annotated further with the instructor's grades and comments attached to individual testing items, thereby becoming a basic part of the student profile.

The evaluation items are multimodal in the sense that responses to questions may be made in a variety of modes. In the case of tests, the student can answer true/false or multiple-choice questions by pointing and clicking as in traditional electronic testing. Test takers can also key in editable answers to essay questions, and use a stylus to draw pictures or to provide hand-written responses, as when working math problems. The electronic drawing scheme provides an eraser that allows students to erase and re-enter work.

Figure 1 presents a depiction of the interface to the testing component. Figure 1a presents the student's view of the test. In question 7, the student is required to draw the picture of an AVL tree, a typical data structure. The student will compose a computer program function in question 8, fill in the blank in question 9, and answer question 10 (the true/false question) with a click of the mouse. Figure 1b illustrates the instructor's view of the test. The student's hand-written answer to question 7, and the code the student wrote in question 8 are visible. The instructor can see the attributes associated with the question – the topic area, and the ratings on the dimensions that are tested.



7. Nodes are added into an AVL tree in the following order:

K, L, M, P, A, G, R, S Draw the resulting tree here

8. Write a hash function that takes a string as a key value.

9. Quicksort has a worst-case performance of:

10. A sort of O(n log n) is always preferable to a sort of O(n**2).

○ True ○ False

8. Write a hash function that takes a string as a key value.

```
long HashClass::HashFunc(string st)
{
  long asciiValOfChars = 0;
  for(int i = 0;i < st.length;i++)
    asciiValOfChars += st[i];
  return (asciiValOfChars % TABLE_SIZE)
}
```

Topic Hashing Theory 0 Design 0 Programming 5 Code Tracing 1 Debugging 0

Figure 1b. The instructor's view of the exam.

In question 7, the topic area is AVL trees, and the possible dimensions are theory, design. programming, code tracing and debugging. Topics and areas are domain-specific. Question 7 requires that students understand the theory of insertions in an AVL tree. Question 8 requires that the student be able to program a function that is part of the process of hashing. It is possible that more than one dimension might be addressed in a question, in which case there would be more than one non-zero value in the annotations. The instructor is provided with a space to assign the score and to annotate the question with comments in the "score" and "comments" fields. The areas and dimensions associated with the various questions are utilized along with the scores in order to assemble the student profile, which is discussed in the next section.

BEST COPY AVAILABLE

Student Models and Profiles

Figure 2 depicts the visual component of a profile from a course in Data Structures. In conjunction with the testing component, the profile is created automatically. The tool provides further capability to edit the profile manually. In Figure 2, the dimensions appear as the rows and the areas appear as the columns. A Likkert scale is presented for the scores in a given area/dimension combination, with a range of 1 (low) to 5 (high). The visual representation makes it easier for the student and instructor to determine how the student is progressing. For example, Figure 2 illustrates that the student is doing well in the theory component of the course, but poorly in the programming.

Profiles emerge over the duration of the course. Initially, little information is available. If a course is treated on a topic-by-topic basis, the columns fill in as tests, quizzes and homework assignments are evaluated. Profiles can be aggregated over multiple courses if some of the dimensions of achievement are shared between the courses. Individual area or dimension scores can be collapsed to give an overall score for, e.g., "Programming" or "Sorting." Profiles can be viewed for individual students, aggregated for an entire class, presented as comparisons between classes, and aggregated by students who have similar weaknesses or strengths. These aggregations can be used to create a visual representation of how the entire class is doing, to set specific remediation groups, or to group students in a way that has a combination of stronger and weaker students in the same group.

Summary

This work describes AMEE, an Annotated Multimodal Electronic Evaluation system that allows the instructor to annotate evaluation items and generate student achievement profiles that can be viewed by both the student and instructor. The motivating idea is to present a visual depiction of student progress in a course. This depiction can be used for face-to-face or distance learning courses. Students can view their profiles to determine the progress they are making in the course.

The system starts with the testing component that allows students to answer traditional computer-based questions such as true/false and multiple choice. Additionally, AMEE allows students to key answers to essay questions and to create hand drawings with a stylus. Questions have annotations that indicate the areas (topics) of the course that the question evaluates, and the dimensions of attainment within an area. The visual tool allows the student and the instructor to see at a glance how the student is performing in the course. Additionally, the instructor can aggregate data on classes to view how the whole class is performing, to identify students with similar strengths and weaknesses, etc.

Developing a Virtual Community of Learners

Susan M. Colaric, PhD
School of Education
East Carolina University
Greenville, NC, USA

Abstract: People have been gathering in communities for centuries. Initially for protection, then socialization, these groups tended to be small, focused on the villages of an agricultural society. In the 19th century, with the changes in daily lives brought about by the Industrial Revolution, the purpose of communities changed. As we move into the Information Age, virtual communities have formed, including virtual communities for educational purposes. These new communities offer participants an opportunity to move beyond physical location to interact in a global community, yet many people are ill-prepared to meet this new challenge. The modes of communication and social mores of the group are foreign, with both instructors and learners unsure of how to act in the new environment. While the potential exists for online educational communities to fulfill the goal of extending education beyond the walls of the campus, both instructors and learners need assistance in becoming full members.

It is difficult to develop a singular definition of community. In biological terms, community refers to an interacting group of species in a common location. Synecology, in fact, is the study of a group or community of organisms and their relations to each other and to their common environment. So physical existence in a common area (co-location) is the key. However, most dictionary definitions do not stress co-location; the important factor there is the association of interests; communities are formed around a common interest or goal.

Ferdinand Tönnies, an early German sociologist, in *Gemeinschaft und Gesellschaft* (1887; translated as *Community and Society*, 1957), sought to explain the major social problems in the West as a consequence of the transition from the communal, status-based, concentric society of the Middle Ages to the more individualistic, impersonal, and large-scale society of the Industrial Revolution. This was, in fact, a way of differentiating communities based on factors of co-location and communal interests. He explained this through the distinctions between the local community (gemeinschaft) and the larger society (gesellschaft). Gemeinschafts are "small, geographically distinct, kinship-interwoven groupings characterized by intimate, overlapping, and stable relationships" (Hiltz & Wellman, 1997, p. 45). Gesellschafts are formed by a larger, disperse membership who are oriented toward a particular goal. He believed that the duality of these two concepts is present in everyday life and is distinguished by the separation of community and mere association.

Steven Jones in *Virtual Culture: Identity and Communication in Cybersociety* (1997) begins with the biological definition of community but also goes a step further. He believes that community relies on "inhabitance, not just being in the same place at the same time with others but as being a part of that place, as if one is part of the landscape" (Jones, p. 16). He, in fact, removes the idea of interest stating communities are "parallel, rather than serial, groupings of people, which is to say that they are not composed of people who are necessarily connected, even by interest, but are rather groupings of people headed in the same direction, for a time" (Jones, p. 17).

The idea of the university as a community is often expressed: community of scholars; higher education community; the campus community. Ernest Boyer, a prominent researcher investigating the role of higher education in American society, edited a report for the Carnegie Foundation for the Advancement of Teaching and the American Council on Education entitled *Campus Life: In Search of Community* (1990). In it he reported the results of a survey conducted among college and university presidents which focused on social conditions on campuses. The study had as its focus the community aspect of higher education. Boyer distinguishes between six elements of community on campuses:

> First, a college or university is an educationally purposeful community where faculty and students share academic goals and work together to strengthen teaching and learning on campus

> Second, a college or university is an open community where freedom of expression is uncompromisingly protected and where civility is powerfully affirmed
>
> Third, a college or university is a just community where the sacredness of the person is honored and diversity is pursued
>
> Fourth, a college or university is a disciplined community where individuals accept their obligations to the group
>
> Fifth, a college or university is a caring community where the well-being of each member is sensitively supported and service to others is encouraged
>
> Sixth, a college or university is a celebrative community, where the heritage of the institution is remembered and where rituals affirming tradition are widely shared (Boyer, 1990 p. 7-8)

Here, Boyer is using the definition of community which emphasizes a shared interest since there is no mention of co-location.

When the discussion moves to virtual communities the definitions become even less clear because there is the added dimension of co-location being in a virtual space. Virnoche & Marx (1997) define virtual communities as "those encompassing people whose connections to one another are based solely in virtual space or on computer-mediated communications" (Virnoche & Marx p.86) where the members share a virtual space but never a physical one. There is no mention of sharing common goals or interests; the idea of co-location is there but it is a virtual space. So the question becomes, can you share a common space when in fact you are not physically located together? Virnoche & Marx are also very clear in stressing that the members *never* share a physical space. Rheingold (1993), on the other hand has a different perspective as he considers virtual communities to often include an "In Real Life" (IRL) element. He defines virtual communities as "social aggregations that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace" (Rheingold, p. 5). So his definition focuses more on the shared interests, with elements of longevity and inter-personal connections added.

Hiltz & Wellman (1997) in their study of Asynchronous Learning Networks (ALNs) also use a definition based on shared interest. They, in fact, view the lack of co-location as a positive element of virtual communities:

> Because they are less constrained by geography (and group solidarity) than traditional communities, spatially dispersed communities in general, and virtual communities in particular, tend to be communities of shared interest. The ease of contacting other people facilitates the growth of relatively large virtual communities and the evolution of densely knit relationships among community members. The lack of traditional spatial and group constraints means that virtual communities are often heterogeneous in social characteristics, such as lifecycle stage, gender, ethnicity, and socioeconomic status. (Hiltz & Wellman, p. 45)

Douglas Scholer in *New Community Networks: Wired for Change* (1996) advocates changing the definition of a community completely. "The old concept of community is obsolete in many ways and needs to be updated to meet today's challenges. The old or "traditional" community was often exclusive, inflexible, isolated, unchanging, monolithic, and homogeneous. A new community ... needs to be fashioned from the remnants of the old" (Scholer, 1996, p.9). He believes communities are strictly goal-oriented and states that "communities are not places to be, to engage in conversation, they are groups of people seeking to achieve particular goals". This is a departure from the contemporary definitions of community because co-location is no longer a concern and a shared interest is not sufficient -- there needs to be a goal that the group is working toward. It does, however, reach back to Tönnies' concept of *gesellschaf.* This definition seems to fit most educators definitions of virtual universities although they are also hoping for the communal feelings of *gemeinschaft*.

As with other definitions of communities there is no consensus on what clearly defines a virtual educational community. Early, some would say idealistic, definitions echoed the sentiments of Rachel Schwartz (1995). "The Virtual University is a university where, with the help of technology, students have access to the world's best instructors and information sources without having to set foot on campus" (Schwartz, 1995, p.26). The definition is a loose one including conversation and probably a shared interest but the concept of co-location is not addressed. Michael Brooks (1997) attempts to operationalize the term in "Beyond Teaching and Learning Paradigms: Trekking into the Virtual University"

> "By virtual education, I mean education that is enhanced by the application of electronic technologies to the processes of teaching and learning. Education becomes virtual to the extent that teachers and learners, who may interact in the traditional classroom mode, are joined in the learning process electronically, possibly across great distances, such that teaching and learning are no longer tethered to a single place, time or pace. Virtual education, therefore, includes traditional modes of learning supplemented by the use of sophisticated technologies, including personal computers, networks, and perhaps the Internet, plus what is known as distance learning, or learning that does not involve a students being physically present on the home campus of the school offering the course. (Brooks, p. 7)

This very broad definition includes the possibility of co-location but doesn't require it; it includes a shared interest (the learning of the subject); and there is an element of interaction. Hiltz and Wellman (1997) appear to share the same concept:

> "A virtual classroom is both an instrumental group – in which students and instructors want to accomplish goals – and a community – in which students exchange emotional support, information, and a sense of belonging. Asynchronous Learning Networks are best at enriching educational options when they serve as a way to create the feeling of a true "class" or group of people learning together and to structure and support carefully planned collaborative learning activities that constitute the assignments of a course. Emphasizing group cooperative efforts among faculty and students, collaborative learning stresses that the educational process occurs through the active participation of students and instructors in an environment that facilitates peer interaction, evaluation, and cooperation." (Hiltz & Wellman p.46)

Jack Wilson, Dean of Continuing Education at Rensselaer Polytechnic Institute also doesn't see the displacement of time and space as incompatible with interaction, "The technology will enhance and allow interactions. They don't necessarily have to be at the same time" (Schwartz, 1995, p.25). But he does suggest that there needs to be an adjustment as to the method of instruction. "The faculty's role is not just telling students information – it's to structure information and structure interactions with that information so students can learn material by suggesting, probing" (Schwartz, p.26).

While the idea of building a virtual community of learners seems possible, today's faculty members do not have a skill set that they can utilize to accomplish this goal. Most higher education faculty members are hired for their content knowledge, not their ability to bring about a new paradigm of learning. Practical skills, to take advantage of new technologies, based on a review of community development will be the focus of this session. Instructional strategies to facilitate both synchronous and asynchronous communication will be included. Perspectives from faculty members who have employed these techniques in various domains and the views of students in the courses will also be presented.

How Does A Sales Organization Best Support A Distributed Sales Force From A Learning, Communication And Support Standpoint?

The proliferation and advancement of technology throughout the 90's and into the 21st century, as well as global competition have transformed the way business is conducted in the industrialized world. Sustainable competitive advantage is no longer based on technology or machinery. Corporate leaders are saying, "People are our most important advantage." In Canada specifically, many of the global organizations operate as sales organizations. One of the biggest challenges faced by these organizations is keeping their distributed sales force trained and up to speed on potentially hundreds of complex products that can evolve/change on a regular basis. As well, these organizations are challenged with providing "soft skills" learning such as consultative selling, relationship building and self-management.

Companies have traditionally operated on the centralized event-based training model. This approach to learning has proven to be extremely costly, inflexible in terms of time and place, and often fails to meet the goals of the sales force and ultimately the business goals of the organization. The last two years have seen a movement to a more dynamic learning model. Learning Management Systems and eLearning are providing pieces of this yet unfinished puzzle. The next step is to bring it all together in and end-to-end approach that leverages both technology and people to bring learning and performance support tools to the sales organization in a timely and flexible manner.

This paper and presentation will examine how a leading automotive company has developed a robust learning solution that supports a 19,000 + sales force across Canada in their on-going learning and information needs. Specifically we will examine:

- Performance-centered learning model
- Measuring results - how the learning solution supported the measurable performance outcomes and became the benchmark of success
- Blended learning (mixing facilitated learning, eLearning, satellite and self study) to support specific needs
- Product knowledge strategies for ensuring the sales force are constantly updated and competency is assured
- Certification
- Real-time support – selling processes and product knowledge

David Connal, MBA, B.Ed. B.Sc., Manager, Learning Solutions, Maritz Canada Inc.

David has over 14 years experience as a management and performance consultant, instructional designer, and teacher (high school and university). He has designed a wide variety of instructional and informational products including interactive multimedia courseware, and web based performance support tools. As well he has undertaken evaluation and needs assessment studies including strategic planning initiatives and business case development.

Carlo Pirillo, B.Eng, Director, e-Business Solutions, Maritz Canada

Carlo brings over 20 years of IT experience in various industries such as personal security, logistics, high tech and automotive. He has led a team in the design, development and deployment of a Web-based Training Management System that enabled the client to manage training using real-time data, incorporating on-line certification testing, on-line product knowledge, planning modules and course scheduling, automated tracking of individual training histories and training path management, and reporting functions.

Carlo oversees all e-Commerce initiatives and develops IT and e-Business strategies. Understanding the strategic role of IT and the Internet, he works with clients to formulate the appropriate solution to meet their e-commerce needs.

Accessibility in complex web based learning applications: lessons from the PEARL project

Abstract: This paper reports approaches promoting accessibility for disabled students to science and engineering practical work, developed in a major European educational technology project PEARL. This project has developed the facilities for conducting a range of teaching experiments in science and engineering subjects at higher education level remotely over the WWW. This paper concentrates on one example of these, based on the remote control of an optical spectrometer. It gives a succinct view of the overall systems architecture and the user interface sub-system. The approaches adopted to promote accessibility for disabled students are outlined. Lessons from this work, which are generalisable to other Web based applications, particularly with JAVA based clients, are highlighted.

Introduction

The PEARL project (Practical Experimentation by Accessible Remote Learning) started in March 2000. Cooper, et. al. (2000) introduced the project in detail; only a brief introduction is included here to set the paper in context. The PEARL project objectives are:

- To develop a flexible system enabling students to conduct real-world experiments remotely over the WWW.
- To research the pedagogic impact of this approach validating its developments in different educational contexts and subject areas in higher education.

Key results of project are four instantiations of the PEARL approach, one at each of the participating universities. These are realized through a systems integration of: a remote controlled lab facility, a control and communications infrastructure working over the Internet, an accessible user interface sub-system and synchronous collaboration tools. A key deliverable, planned for February 2003, is the PEARL Handbook designed to enable other institutions to adopt the PEARL approach in their teaching. PEARL is a major project with a total effort over the 3 years in excess of 30 person years and a budget of about US$2 million.

PEARL, from its conception, was seen to provide significant potential for enabling greater access for disabled students to practical work in science and engineering subjects. This paper describes in particular the instantiation of the PEARL approach developed for the Open University. It is around this prototype that the accessibility work in the project has been concentrated.

The accessibility rationale

Disabled students are grossly underrepresented in the science and engineering disciplines. The reasons for this are complex and include significant factors from primary and secondary level education. However access to experimental work is cited as a key barrier in analysis of this problem both in North America and Europe. Much work has been done over the past 20 years to make computers accessible to people with all kinds of disabilities. Hence the approach in the PEARL project has been to firstly to make practical work computer controlled. It then had to ensure that the computer software and interface design followed well-established design for accessibility principles, as exemplified by the WAI Content Guidelines [URL 1] or various manufacturers' guidelines [e.g. URL 2, URL 3] and that the software was compatible with the available access technologies.

The system developments

The overall approach to the systems architecture has been a modular one so that the different modules can be readily adapted when creating a new experimental facility. It is a CORBA based architecture which means that these modules can be mapped onto physical machines in a flexible fashion as dictated by other design constraints. For the implementation described here there was a Lab Server connected to the remote laboratory equipment, a Web Server that mediated all the communications to/from the students' machines and interacted with the Lab Server and the students' client software over CORBA bridges. The Server application implements the high-level control operations that can be requested remotely. These high-level operations are translated to calls to low-level control methods exposed by the Hardware Access application. The low-level methods are invoked across a local CORBA bridge.

The Remotely Controllable Jig

A simple optical spectrometer has been adapted so that it is motor controlled. An annotated photograph of this is given in **Figure 1**. The spectrometer has been mounted on a moving table so that the students can position it in front of different light sources. Air is bubbled through one of up to 6 different metal salt solutions, as selected by the students, and into the gas feed to the Bunsen burner. Therefore the spectra associated with the chemical in each bubbler can be observed. The slit size and focus of the collimator, used to ensure the light is parallel as it passes into the diffraction grating, have been motorised, as has the rotation of the telescope. The driver circuitry for all the motors, valves and sensors is located together in a dedicated housing. This in turn is interfaced to the Motion Controller Board installed in the Lab Server.

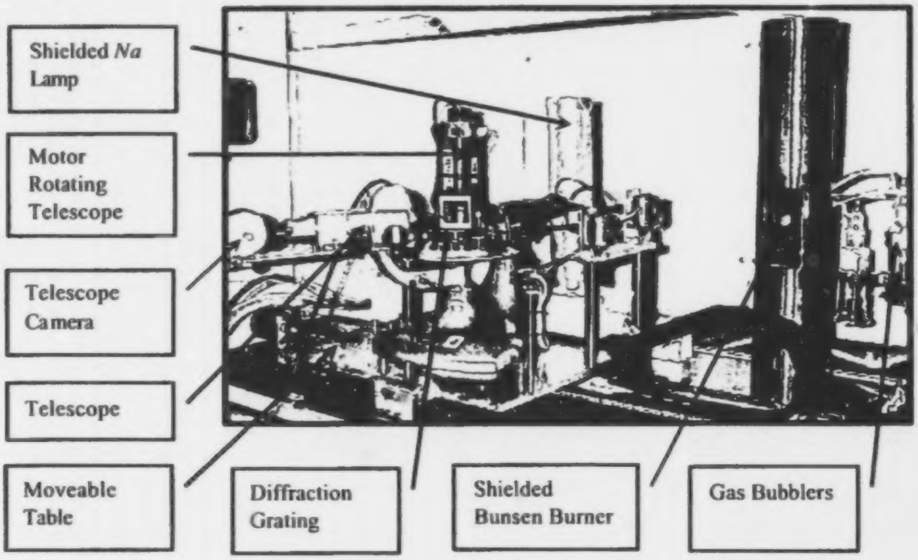

Figure 1: Annotated Photograph of Motorized Optical Spectrometer Jig

User Interface Approach

The user interface design has been conceived in such a way as to promote usability and accessibility and so that it is readily adapted when creating a new PEARL experimental facility. The Client can run either as an application or as an applet within an Internet browser. In fact, to provide support for both formats, only very

Approaches to Achieving Usability and Accessibility

There are several complex issues that need to be addressed in the design of a user interface for remote control of apparatus. The main issue is the impact of delays between the user's operation of a control, and the execution of that command in the laboratory, and the feedback, via the video feeds, that the command has been completed. The design therefore includes buttons, rather than knobs or sliders, to support students in making discrete commands. Students may need to operate any one of up to 20 controls at anytime and therefore these controls need to be readily accessible. The design therefore groups the controls for different aspects of the spectrometer into 'tabs' (similar to Windows property sheets).

Accessibility requirements and solutions

The design incorporates several requirements in order to make it accessible to students with disabilities. These are presented in the table below in bold text, along with a description of how they are met in the design. The requirements were based on guidelines for the accessibility of Web content [ibid. URL 1] and the expertise of the researchers and their colleagues. The below table summarises these key accessibility criteria and links these with notes on how these were implemented in the JAVA based client programmes. In most cases these are generalisable to any interactive application implementing its client software in JAVA.

Accessibility Criteria	Implementation Notes
Inheritance of Windows properties: Some disabled users require or prefer specific settings within the operating system in order to use the computer. (E.g. certain colour combinations, font style and size, or utilities such as StickyKeys).	The client's GUI is based on JFC/Swing components from J2SE v1.4.0, which can track user's display preferences in Windows, such as colours, fonts, metrics, etc, and can also respond to dynamic changes made by the user.
Text labels on all controls: The screen-reading software used by visually impaired users for speech output requires all user interface elements to have text labels which can be read out.	All controls have their Java accessible names set in the code. In addition, the Java Runtime Environment (JRE) used to run the client is configured to use version 1.0.2 of the Java Access Bridge for Windows. Thus, JAWS for Windows v4.0.2 is able to read the accessible names of all controls.
Keyboard operable: Many disabled users cannot or prefer not to use a mouse and therefore need to be able to operate all user interface elements via the keyboard. The PEARL application provides two methods of keyboard operation. The Tab and Enter keys respectively can be used to navigate between, and operate, the controls and keyboard shortcuts enable the user to operate all controls	The order in which the controls can be focused using the Tab key is set by the way in which the controls are laid-out on the GUI. In addition, for each control, a keyboard shortcut is associated (via the control's input and action maps) to a global action object. When a shortcut is used, the global action object determines which action should be taken and triggers that action.
Reminders of shortcuts included in labels: Users are supported in learning the keyboard shortcuts with the inclusion of the shortcut in the label of the control.	The accessible names of all controls include the corresponding shortcut key character, so JAWS may read it.
Auditory indication of command progress: To provide visually impaired users with feedback on the progress of commands, on-speech sounds are provided to acknowledge the system's receipt of a command, and that it is completed. This information is also provided visually for other users in the form of progress bars located beneath each control.	Short sounds accompany the changes in state of the progress bars located below each button. The simple support for sound of the Java core APIs is used to read and emit the sounds from files in WAV format. The CORBA connection between the client and the server is bi-directional, so that the intermediate state of a command ('command acknowledged') may be triggered by an asynchronous CORBA call-back.
Status bar: The status information provided in the progress bars is also presented in a status field. The application focus can be temporarily moved to this field using a shortcut. This enables visually impaired users to query the current status in case they missed the auditory indication.	The status bar is a regular label component which accessible name is dynamically updated, every time the command state changes. Pressing the status bar shortcut key simply diverts the input focus momentarily to the status bar, so JAWS may read it, and then returns the focus to the previous component.

Conclusions

The PEARL project has demonstrated the remote control of complex functionality can be achieved across the Internet. The user interface design for the Open University's Optical Spectrometer is a good exemplar of how widespread accessibility for disabled people can be achieved in JAVA based applets or applications and these approaches are applicable to any interactive software package.

Abstract: This paper presents a Web/Internet-based distance learning environment which allows users to form academic communities through Web. The main idea is to provide means to have virtual communities sharing the same space. In order to help the interactions among different users either from the same or different academic institutes, these communities are comprised of their own synchronous and asynchronous communication tools along with their pedagogical resources, in addition to others to support the invitation of guest users other than academic ones. Our goal is the academic communities; academic subjects of a given department of an institute, which are organized to provide the stated extension, taking advantages of the Internet and the tools developed using it. This paper focuses a particular view of the announced system, that is, an instance of environment oriented to support, on the web, undergraduate courses. The architecture and the functional aspects of this environment are presented.

Introduction

The Internet provides researchers possibilities to develop new communication/interaction tools which support learning communities, specially the academic ones. In this context, we present a particular environment which concerns the forming of academic communities through Web. This environment is called graW (Undergraduate Courses on the Web). Essentially, graW is composed of two categories of computational tools regarding an academic environment. One is concerned with pedagogical aspects, providing resources such as synchronous and asynchronous communication tools along with pedagogical resources. The other is concerned with administrative/support aspects such as user and course register/support. The main idea is to provide an extension of the traditional classroom by using the Internet/Web through virtual communities sharing the same space.

graW Architecture and Environment

The proposed environment has been designed to support the traditional learning space – in our case the academic one – using tools offered by the Internet and others developed at UFAL University. It's based on groups of community which represent either each academic course, presented physically at the academic institute, research groups or any extra course like tutorials. Each community has also their own politics and rights applied to each user, who chooses to be associated with it and share knowledge and information. These users may be teachers and students from any academic environment, and external users that represent the guests of each community. The interactions among the users in each community are managed by a personalized interface which controls the presentation of the community for each kind of user. The community has two types of tools: the communication and the authorship one. A group of administrators can manage the entire environment online. The proposed and used architecture is as follows (Figure 1).

Figure 1: The model of the graW Architecture and the interaction of its different types of users.

The ability of doing something by a user is defined in the personalized interface, which stores information about the user and his preferences on the community he is associated with. Indeed, if a user is a teacher, he has the rights, for example, to post any document to the community or even schedule a chat session among the participants. However, a student could only have access to the generated knowledge of the community.

The environment enables different kind of communities, such as academic subjects, courses and research groups, each of them created by a different kind of user. E.g. a teacher can create an academic subject or any other, whereas students can only create research groups or courses. Each community has its own politics which define the association and visibility. The association policy says how the system acts when a user requests an association.

The communities are also composed by tools to help the participants exchange information easily: the synchronous communication tool that is a chat room with a whiteboard for each community and the asynchronous communication ones, which are the use of a list of emails of all participants, a discussion forum to discuss about any kind of categorized information and the integrated/personal schedule to apply a meeting to all community, for instance, or for personal use.

BEST COPY AVAILABLE

Authoring tools here are designed to provide new contents on the web of the interaction during classes. These contents can be links to other sites and any kind of documents; everything shared with all students on the online environment, and later, they can be indexed with the information of the program of a given community.

The administration tool, which is the main source of graW, is used only by administrators in order to provide the initial content of a given department or even the university. These administrators can also delegate others to work along with them, in order to set a new university in the environment.

There are basically three types of users: the academic, the external and the administrator ones. Each of them has its own characteristics. The academic user is a Student, a Teacher or a Monitor which are interacting in the communities. If it is required the presence of a guest, like someone without any link to the academic course or subject, graW enables that an external user has all privileges as teachers have. Finally the administrator delegates other users to help on the configuration and give all permission on the environment. All of them are distributed in groups by academic courses.

Discussion

Teachers are responsible for proposing communities which are the ones taught by him in the institution. After the approval of the community by an administrator, the teacher can populate the community by using tools like the guest center in order to send emails to users who can be interested in the participation of his virtual community. His community will also be seen by users like students who can choose to join it. Besides, Teachers can "elect" Monitors, among the students associated with one of the communities, to help him in the production of resources and the publication of academic resources like documents, links and so on. This means that the Monitors will have the same ability as Teachers have in the environment.

Like in the real world, sometimes students are in doubt about something they didn't understand in a class or they can be shy to express it, for example. For this reason, graW offers these users the chance to join a community of their preference, in order to get their answers using the communication tools, besides exchanging ideas among the others. As a result, students now have conditions to express their ideas with their classmates, in addition to learning with others who are presented in the same community.

Now suppose that a teacher wants to have a guest to show something to his virtual community. graW enables him to invite another teacher, for instance, a business man, in order to present the community something new. Teachers can invite someone to join the community and share his knowledge among the participants, interacting in a chat session or answer question on the discussion forum. This interaction may stimulate free exchange of ideas among different users.

All described type of users will be able to propose communities. These can be tutorials or extra courses, besides gathering other users in an online environment.

The academic subject is intended to allow academic users to discuss specific issues related to it. It's organized by teachers of the subjects that are being proposed. Teachers have administration tools which allow them to upload information like the course description, bibliography and even its program with the indexing to the correct document or link published with the authoring tool.

There are two types of course: course with a link to an academic subject: It allows the creation of extra curricular courses associated with an academic course. It might be like a tutorial or a course given by a guest teacher in the university the community is in; course without a link to an academic Subject allows the creation of extra curricular courses without any association with universities.

The communication tools are responsible for an easier end faster communication among teachers, students and other users. They make use of tools of two known categories: Synchronous tool, which are a *chat* tool associated with each community, where users can have a real time chat session in order to debate anything with the others. Along with the chat tool, there is a *whiteboard* one to help users to explain what they are talking about just drawing on the board; others are Asynchronous tools, which are the most used tools of graW. It is offered a *discussion forum* for every community in order to enable users to expose your doubts and questions in a secure area where teachers, monitors and other users in the community can discuss, answering and making questions about what is being studied. As a consequence, new information is produced by the community. There is also a *list of all users* and their information, including *email*, associated with a particular community to support a discussion list of email. Therefore any user can send an email to another or even to all participants of the community. Another tool in this category is a personal/shared scheduler, where teachers and monitor can schedule an anything like a test time or even the next chat session of a particular community, in addition to being used as a personal calendar/scheduler.

In order to offer different pedagogical resources, graW has an authoring tool which enables teachers and monitors to publish resources on a particular subject oriented to a given community. In each community, teachers and monitors will be able to upload the required resources and group them. There are two types of resources: Documents and Links. The documents can be of any kind of electronic media like MS PowerPoint Presentation and HTML web pages, each one with a detailed description and additional information; the links are intended to be additional resources in the community, like other web sites of research groups, online content that is of interest of the community or any kind Educational games and simulations.

Conclusions

We have presented the design and development of a learning environment named graW. graW supports learning communities, providing extra-class activities related to specific courses, providing online and fast assistance to students and improving management of classes.

Nowadays, the use graW in our department has provided a great extension of the real classroom works in about 13 different academic subjects, and many others research groups and courses, to more than 335 users, from students to teachers from Federal University of Alagoas, UFAL. Preliminary results have pointed out positive aspects and have doing, at the same time, little adjustments concerning user interface. At the moment, there have been developed learning management tools as well as videoconference ones, to be incorporated in the graW environment, available on http://www.graw.tci.ufal.br.

Abstract. Numerous benefits of student-centered web-based learning environments have been documented in the literature; however the effects on student learning are questionable, particularly for low self-regulated learners primarily because these environments require students to exercise a high degree of self-regulation to succeed. Currently few guidelines exist on how college instructors should incorporate self-regulated strategies using web-based pedagogical tools. The scope of this paper is to to (a) discuss the significance of self-regulation in student-centered web-based learning environments; (b) demonstrate how designers and instructors can integrate self-regulation using web-based pedagogical tools; and (c) redefine the role of the instructor to support the development of independent, self-regulated learners through the use of web-based pedagogical tools.

Introduction

In student-centered Web-based learning environments, the physical absence of the of the instructor coupled with the increased responsibility demanded of learners to achieve learning tasks presents additional difficulties for learners, particularly those with low self-regulatory skills. Consequently, the need to promote effective use of web-based pedagogical tools to support self-regulation processes is paramount. It is suggested that web-based pedagogical tools can scaffold the acquisition of metacognitive skills, and knowledge of plans and goals (McLoughlin & Hollingworth, 2001). Additionally, in student-centered Web-based learning environments, content can be customized to meet individual learner needs, abilities, goals, and other individual characteristics, and learning and motivational strategies can be integrated to help students become self-directed learners (McCombs, 2002). Currently however, few guidelines exist on how instructors should incorporate self-regulated processes using Web-based pedagogical tools. Developing such guidelines will provide more effective instructional designs for student-centered Web-based learning environments, and will help define the role of the instructor in supporting the development of independent, self-regulated learners to ensure successful learning experiences.

Processes of Self-Regulation

Among the key self-regulatory processes affecting student achievement and motivational beliefs are goal setting, self-monitoring, self-evaluating, task strategies (e.g. rehearsing and memorizing and organizing and transforming), help seeking, and time planning and management. Goal setting refers to what the student is trying to accomplish (Schunk, 1983). Research indicates that students who set specific as opposed to general goals, and process goals (methods and strategies that can help one master a task), rather than product goals (outcomes of learning efforts), show high skill achievement and motivation in the initial stages of learning a task (Zimmerman & Kitsantas, 1997; Zimmerman, 2000). Self-monitoring which refers to deliberate attention to an aspect of one's behavior (Kanfer, 1971) directs the learners' attention to the task and assists them in evaluating the outcomes of their efforts. For instance, keeping daily records assists the learner in determining how to make appropriate learning adjustments in order to attain his/her goals. Self-evaluation refers to comparing outcomes of performance with a standard or goal (Zimmerman, 2000). Research studies show that students who self-evaluate their progress, display higher skill acquisition and report higher self-efficacy beliefs, intrinsic interest and self-satisfaction about their performance than students who do not self-evaluate. Task strategies during self-regulated learning include strategies that learners believe will enable them to accomplish their goals. These strategies are domain specific and may include (a) deeper processing elaborative and organizational strategies such as, rewriting notes, selecting main ideas, and/or outlining the text to be learned; and (b) rehearsal strategies for basic memory tasks such as using mnemonics to remember the key stages of a theory. Research evidence indicates that use of appropriate strategies is highly correlated with academic achievement in the classroom (Pintrich & De Groot, 1990). Help-seeking, an important self-regulatory process, refers to seeking help from experts or available resources to assist one self to learn. Findings from numerous studies indicate that help seeking significantly predicts performance (Newman, 1990). Finally, time planning and management refers to budgeting time effectively. Effective management of one's study time also contributes to academic achievement (Zimmerman, 2000).

Integrating Self-Regulation Processes Using Web-Based Pedagogical Tools

Web-based pedagogical tools can be classified into six broad categories ranging from basic to complex, and from specialized or single purpose tools (e.g. creating a web page), to integrated or multipurpose tools (e.g. creating a web page, uploading a web page, sending email, managing student progress, etc.). We briefly describe each of these categories below and discuss their implications on promoting self-regulation processes.

Web-Based Hypermedia Tools

This category includes the use of browsers, search engines, and information navigation and evaluation. Use of these tools may help learners engage in self-regulated learning by assisting them in obtaining relevant information to complete an assignment, and in seeking help when they encounter task difficulties using the variety of resources and search engines supported through hypermedia technology.

Web-based Multimedia Tools

This category involves downloading and installing plug-ins in order to view video/audio files and various multimedia files including graphics, animations, PowerPoint files, PDF files, etc. These tools support meaningful interaction with content by providing learners with multiple options to view or to access the course material in various multimedia formats resulting in higher intrinsic interest in the material.

WWW Publishing/Programming Tools

This category includes the use of HTML editors and other Web publishing and authoring tools (e.g. Dreamweaver and FrontPage). These tools can serve as powerful learning strategies enabling students to demonstrate their understanding of course content by creating Web pages that synthesize their knowledge, or by designing more complex Web-based applications in a collaborative effort. Acquiring such skills helps learners in selecting appropriate task strategies to accomplish process and outcome goals. Use of these tools also promotes self-monitoring and self-evaluation processes.

Asynchronous/Synchronous Communication Tools

This category includes communication tools such as email, discussion forums and newsgroups, chat programs, audio and videoconferencing tools, electronic whiteboards, groupware, and document sharing tools. Use of these tools helps learners engage in an active and reflective dialog with peers and meaningfully interact with relevant resources and learning objects. These tools also facilitate the establishment and refinement of individual and group learning goals; promote the development of effective time planning and management skills to efficiently carry out the responsibilities associated with being an active and accountable member of a group; and encourage student help seeking behaviors.

Presentation and Visualization Tools

This category includes media creation tools such as PowerPoint, Adobe Photoshop, Adobe Acrobat, Inspiration, Mind Mapper, and MindMan, that allow learners to synthesize content through the creation of multimedia presentations and products, and to organize their learning using concept mapping tools such as Inspiration, Mind Mapper ™ and MindMan[1]. In terms of self-regulation, use of these tools facilitates implementation of task strategies including organizing and transforming, structuring, elaborating and rehearsing.

Web-based Course Management Tools

This category emphasizes the use of Web-based applications that integrate multimedia and hypermedia pedagogical tools, asynchronous and synchronous learning tools, presentation and visualization tools, and WWW publishing and authoring tools. Examples of Web-based course management tools include WebCt, BlackBoard, Lotus LearningSpace, First Class, and WebMentor among others. Due to their integrative nature, Web-based course management tools can support all of the learning activities and associated self-regulation processes discussed above, facilitating student-centered Web-based learning and promoting independent, self-regulated learners. Table 1 shows examples of how each class of Web-based pedagogical tools can be used in a Web-based learning environment to support the processes of self-regulation.

Processes of Self-Regulation	Examples of Instructors' role in Supporting Self-Regulation	Associated Web-based learning Pedagogical tools	Examples of Students' Use of A Technological Tool

---

[1] Inspiration, Mind Mapper and MindMan are computer-based visualization tools that allow users to create concept maps, semantic networks, outlines, graphic organizers and other comprehension monitoring activities. Concept maps are diagrams that represent concepts and relationships structurally.

Goal setting	Help students to identify and set learning goals	Asynchronous & synchronous communication tools	Students use email to communicate goals to instructor and receive feedback
Task strategies (e.g., organizing, transforming)	Help students to select appropriate learning strategies	Presentation and visualization tools	Students use concept mapping software to organize course content
Self-monitoring	Help students to monitor their progress	Web-based course management tools	Students use the "your progress" tool to monitor their progress on learning tasks
Self-evaluating	Help students to evaluate their progress	WWW publishing & programming tools	Students use online rubrics, and evaluation criteria to make a judgment
Time planning and Management	Help students to develop effective time planning and management skills	Asynchronous & synchronous communication tools Web-based course management tools	Students follow posted protocols on how to participate in moderated online discussions to budget their time Students use electronic calendar to plan semester activities
Help-seeking	Help students to identify social and non-social sources	Asynchronous & synchronous learning tools Web-based hypermedia tools	Students use an electronic listserve to post a question Students use a search engine to obtain information
Intrinsic Interest	Help students to interact meaningfully with content material	Web-based multimedia tools	Students use graphics, audio, and video to view and process learning content

Table 1. Mapping Web-based learning Pedagogical tools to Self-Regulatory Processes

Rethinking the Instructor's Role in Supporting the Development of Self-regulated Learners in Student-Centered Web-based learning Environments

The success of any distance education program rests squarely on the shoulders of the faculty (Willis, 1995). Willis believes that instructors in web-based learning environments face a number of challenges. Some of these challenges include difficulty in (a) understanding the characteristics and needs of distant students with limited or no face-to-face contact; (b) adapting teaching styles which take into consideration the needs and expectations of multiple, often diverse, audiences; and (c) developing a working understanding of delivery technology, while remaining focused on the teaching role. Because of these challenges the instructor's role in web-based learning environments must be reconceptualized to meet the needs of student-centered learning, and to support students' use of web-based pedagogical tools to assist them in developing self-regulatory skills. In an effort to identify the roles and competencies of distance education professionals, Thach and Murphy (1995) conducted a review of the distance education research literature. Seven critical competencies or skills emerged that can be used as a framework for rethinking the instructor's role in web-based learning environments. They include (1) interpersonal communication and feedback, (2) promoting interaction, (3) administrative and support service, (4) collaboration and teamwork, (5) knowledge of conducting a needs assessment, (6) understanding new learning pedagogical tools and their impact on learners, and (7) developing a systems perspective of thinking. All of the above competencies require instructors' proficiency in the use of web-based pedagogical tools. The authors however did not provide guidelines on how instructors can implement these competencies using web-based pedagogical tools. Additionally, by encouraging instructors to develop these competencies, particularly those related to communication, feedback, interaction, and knowledge of conducting a needs assessment, instructors will be able to support self-regulated learning in the student-centered web-based learning environment. Due to space limitations we will not be able to describe each of these competencies in detail however we will provide a few examples on how instructors can apply some of those competencies in student-centered web-based learning environments to support students' development of self-regulated learning skills.

For example, regarding the first competency (interpersonal communication and feedback), instructors can use email to discuss individual student goals and expectations at the start of a web-based learning experience. This form of communication establishes a sense of security, direction and purpose that is much needed in the absence of face-to-face instructor-student interactions. With respect to the second competency (promoting interaction), instructors can set up an electronic listserve aimed at supporting students' help-seeking behaviors (see table 1). Students can post technical, pedagogical, or administrative questions to this listserve, andobtain feedback from the instructor, their peers, and technical support staff assigned to assist the instructor in the web-based learning environment. This listserve can also promote collaboration between the instructor and the technical support staff,

BEST COPY AVAILABLE

which was emphasized as an important competency in distance learning programs. Additionally, instructors can promote interaction and collaboration by setting up structured and moderated discussion forums using Web-based course management tools. Structured and moderated discussion forums allow students to engage in meaningful discourse and to test the viability of their ideas and interpretations of content material on others (peers and instructor). Well-defined protocols on how to moderate, post to, and synthesize online discussion forums should be clearly communicated to students using for example the "course assignments" or "course activities" features of the web-based course management tool. Web-based rubrics on how students' contributions will be evaluated should also be provided. Additionally, instructors should plan on facilitating at least one or two discussion forums to model the implementation of such protocols and to demonstrate how to effectively synthesize an online discussion in order to promote meaningful understanding of course content. Conveying appropriate protocols to students and modeling the implementation of protocols and procedures in a web-based learning environment helps students develop effective time planning and management skills (see table 1). Furthermore, the instructor's competent use of presentation and visualization tools (e.g. concept mapping tools, PowerPoint presentations, and the constructing of tables and matrices) to demonstrate how to synthesize an online discussion assists students in selecting appropriate task strategies to organize and structure their learning (see table 1).

Conclusion

The success of any learning environment is based on the careful analysis of learner and instructor skills and the strategies and tools used to deliver and manage effective instruction. This paper examined the interaction between web-based pedagogical tools, learners' processes of self-regulation, and instructor competencies deemed critical in identifying the instructor's role in web-based learning environments. It is suggested that the deliberate orchestration of these three components may lead to the development of independent, self-regulated learners in student-centered web-based learning environments. By carefully mapping the use of web-based pedagogical tools to the processes of self-regulation, and helping instructors develop competencies that promote the implementation of learner-centered instructional and learning activities through the use of such tools, web-based learning environments can become increasingly student-centered and learners will become better prepared to assume responsibility for their own learning and face the changing nature of distance education programs.

REDI: On-Line Educational Resources for the Development of Professional Multimedia Skills.

Ricardo Dal Farra
National Institute for Technology Education
National Ministry of Education
Buenos Aires - Argentina
ricardo@dalfarra.com.ar

Abstract: The National Institute for Technology Education from the National Ministry of Education in Argentina began a few years ago to work on new educational profiles trying to integrate the complex necessities of the work world of today with the basic concepts that the school should transmit to students. From those profiles were developed a group of modular curriculum structures being applied in our country now, an example being the Technical Vocational Pathway in Multimedia Communication based on a competences learning process. An educational program at the national level focused on the development of professional skills needs to solve several problems to work this out, being faculty training on new areas of knowledge and work a big issue. The answer was REDI, an on line educational database with resources, activities, documents and didactic strategies being produced focusing the technical competences and artistic skills needs for multimedia and related medias.

Introduction

During 1996, the National Institute for Technology Education, part of the National Ministry of Education in Argentina, began to work on new educational profiles trying to integrate the complex necessities of the work world of today with the basic concepts (in a broad sense) that the school should transmit to students.

One of the biggest differences between this and previous programs, was the work over a competences based learning approach. Starting from the identification of real and potential professional competences required for different occupational areas, the next step was to elaborate the educational profiles that looks for the present and prospective needs of a person who is now studying but will be soon working on a medium with highly changeable technological environments.

As soon as new educational profiles began to be developed, several problems arose, and among them were the lack of teachers with both the technical instruction for the work and the pedagogical preparation for the class.

The development of didactic resources is a requirement to help the transformation processes to improve education, and are of special importance if we think on new fields where integrated technical, scientific as well as artistic capabilities needs to be developed.

Multimedia Communication

From those original profiles were developed a group of modular curriculum structures being applied in Argentina since 1999, an example being the Technical Vocational Pathway in **Multimedia Communication,** based on a competences learning process.

The dynamic growing of the multimedia professional field requires to be prepared to integrate art concepts with specific contents and fast changing technologies.

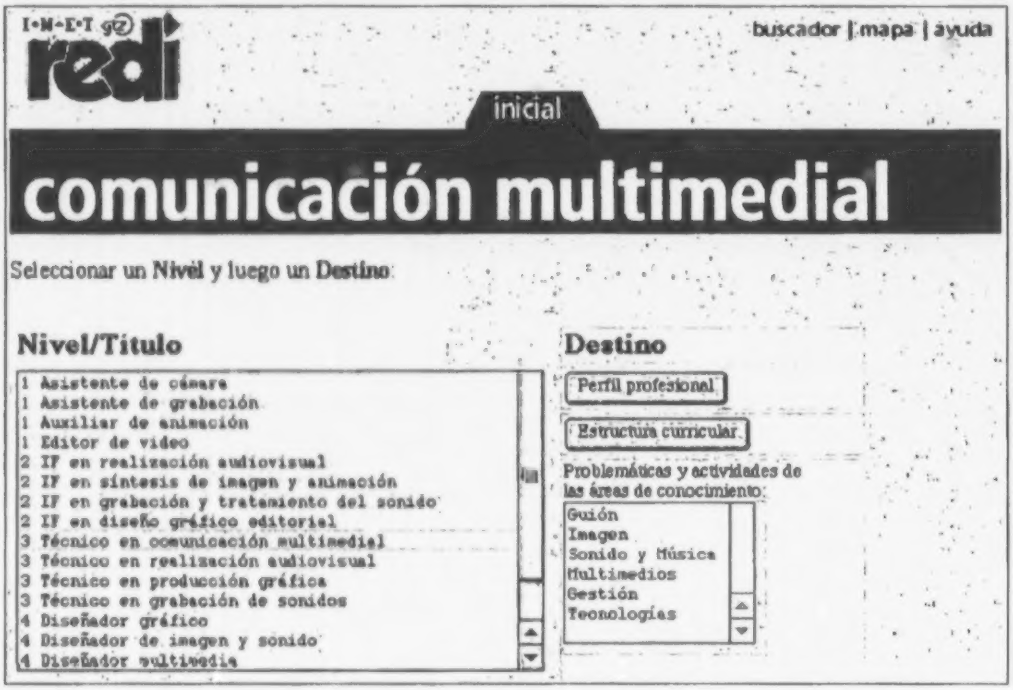
Is not possible to develop a cultural change on the educational system just writing new plans. An educational program at the national level focused on the development of professional multimedia skills needs to solve several problems, being faculty training on new areas of knowledge and work a big issue.

Our answer to this was REDI, an on-line educational database with resources, activities, documents and didactic strategies being produced to focus on the technical competences and artistic skills needed for the multimedia and related media fields (image synthesis and animation, sound editing/processing, video, etc.).

The REDI project

The REDI project (REDI stands for *recursos didácticos* in Spanish = didactic resources in English) is focused on the development of educational materials for the competences based learning process on multimedia and related medias.

On REDI, capabilities, problematic situations, activities, didactic strategies and contents can be accessed selecting a Professional Qualification level, a Professional Profile, or the Knowledge Area related to the specific multimedia subject searched.



comunicación multimedial

Seleccionar un Nivel y luego un Destino:

Tecnologías

Figure 1: REDI have several options to explore and search for its contents. To navigate it, is possible to start choosing a qualifying level or certification/diploma/degree, a professional profile or one curriculum structure. There is also a search engine, as well as a map of the full site structure to help quick findings.

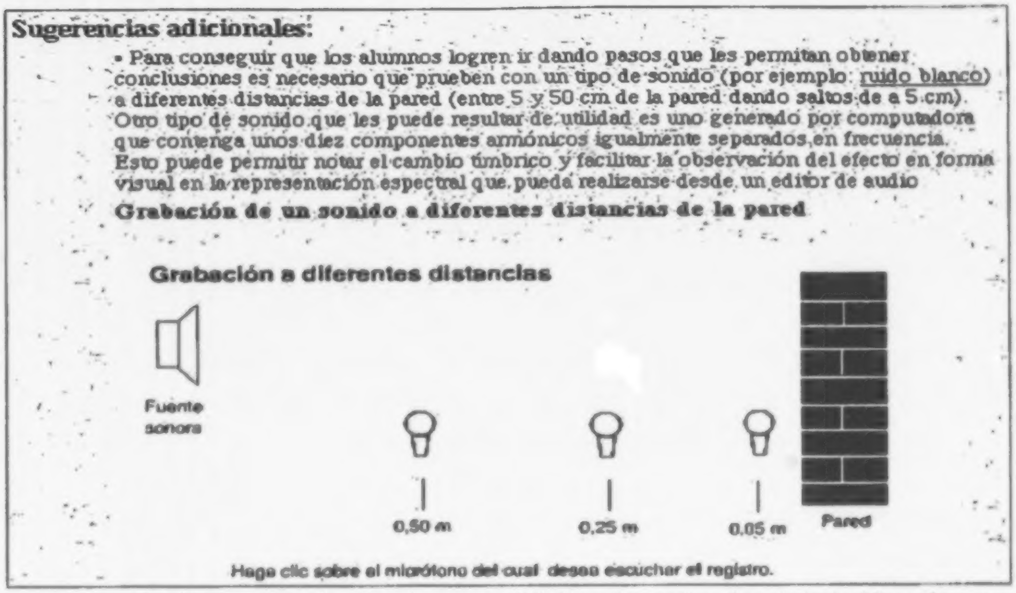
The interactive developments on REDI points to assist teachers or help students to understand problematic situations that can be part of real life practices.

The Knowledge Areas included are: Communication, Multimedia, Script, Image, Sound and Music, Management and Technology.

Ideas and proposals for teachers to work on the class with specific problems on different topics, as well as suggestions for assessments for each area, are going to be included on the final version.

The following figure is a sample of it. Simple but effective, the teacher could use this interactive screen to support a sound recording class. On the example, a sound coming from the speaker is reaching the wall, reflecting, and sounding different when direct and reflected waves are combined. Using REDI this can be easily heard clicking on the speaker to listen to the direct sound source, and then the several microphones placed at 0.05, 0.25 and 0.50 meters from the wall to listen to the different timbres produced by consequence of direct + reflected waves.

BEST COPY AVAILABLE



Sugerencias adicionales:

- Para conseguir que los alumnos logren ir dando pasos que les permitan obtener conclusiones es necesario que prueben con un tipo de sonido (por ejemplo: ruido blanco) a diferentes distancias de la pared (entre 5 y 50 cm de la pared dando saltos de a 5 cm). Otro tipo de sonido que les puede resultar de utilidad es uno generado por computadora que contenga unos diez componentes armónicos igualmente separados en frecuencia. Esto puede permitir notar el cambio tímbrico y facilitar la observación del efecto en forma visual en la representación espectral que pueda realizarse desde un editor de audio

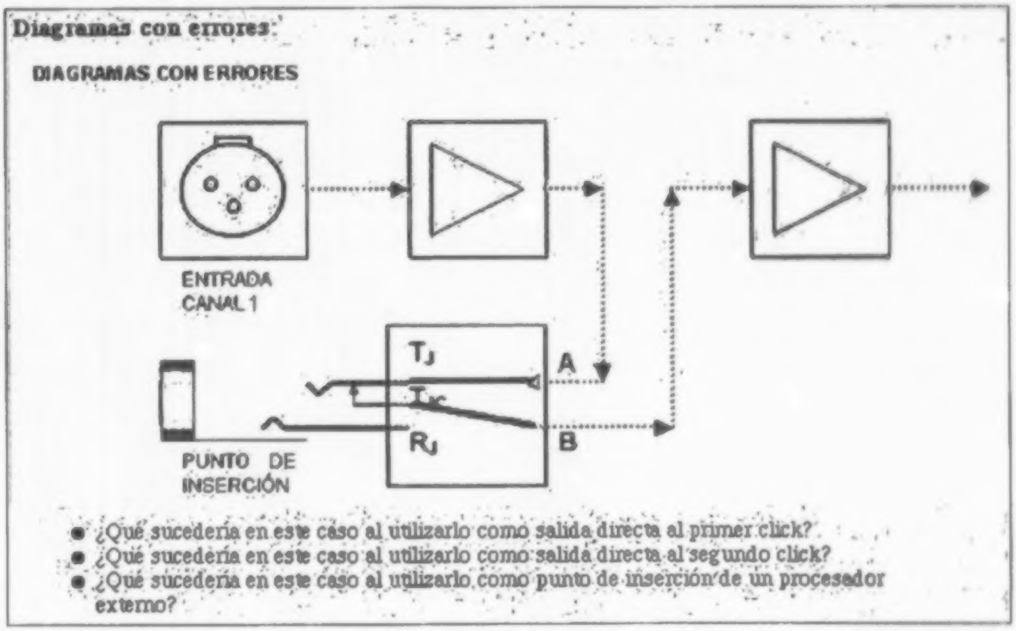
Grabación de un sonido a diferentes distancias de la pared

Haga clic sobre el micrófono del cual desea escuchar el registro.

Figure 2: Sample of interactive educational resource. Clicking the speaker the original white noise source sounds; clicking each microphone the source plus reflected waves sounds (image taken from REDI prototype).

The next sample is a figure presenting part of a problem about interfacing.

Incomplete as well as "wrong" diagrams can be electronically distributed or printed by teachers to their students, who should then fill them and/or explain the correct settings and the consequences on each case.



Diagramas con errores:

DIAGRAMAS CON ERRORES

- ¿Qué sucedería en este caso al utilizarlo como salida directa al primer click?
- ¿Qué sucedería en este caso al utilizarlo como salida directa al segundo click?
- ¿Qué sucedería en este caso al utilizarlo como punto de inserción de un procesador externo?

Figure 3: Sample of a class activity that teachers could print and distribute to the class or students could directly download from the REDI web site (image capture taken from REDI prototype).

BEST COPY AVAILABLE

Additional contents included on REDI are: functional block diagrams, schematics or electronic circuits of typical equipments and systems used in multimedia and related media production, photographs, videos, animations, sound effects, music clips, multi platform freeware and shareware, and even full (free distribution) books.

The development of the first phase of this project, ending with the REDI prototype and evaluation, was possible thanks to the collaboration between the National Institute for Technology Education of Argentina and the German Agency for Technical Cooperation GTZ, with additional support from Apple Computer, Inc.

Conclusions

Tests with teachers and students at schools where the Technical Vocational Pathway in Multimedia Communication are implemented in Argentina are showing very positive results.

This evaluation process of the actual prototype by teachers, students, multimedia experts and industry professionals are helping to improve the different elements of a living system as REDI.

The competences teaching/learning approach adopted to organize the structure of REDI seems to be useful for all educational levels. REDI could be used as a powerful but easy to use database for high school, vocational and higher/university studies as well as for professional training and certifications.

A tool like REDI could help to improve the educational qualities in economically under developed countries where massive access to information, tools, researches and selected medias would be a wonderful help to support the teaching-learning process.

Being today a prototype (originally produced during 1999), we expect to make REDI widely available during 2003 through Intranet/Internet access .

The REDI approach is also triggering international projects being developed now to support education of multimedia and new media art fields.

QuikQuiz©: Complementing WebCT Tools for More Learner Interaction

Michael M. Danchak, Computer Science, Rensselaer Polytechnic Institute, USA, danchm@rpi.edu

Joshua T. Pedersen, Computer Science, Rensselaer Polytechnic Institute, USA,
joshua_t_pedersen@yahoo.com

Abstract: In many face-to-face classes, instructors throw out informal questions to students to encourage interactivity and gauge comprehension. Tools to support this technique are not typically available, especially ones that are compatible with WebCT. This paper describes a tool called QuikQuiz© that allows instructors to embed either discussion or multiple-choice type questions in their content and use the results in either asynchronous or synchronous mode.

Introduction

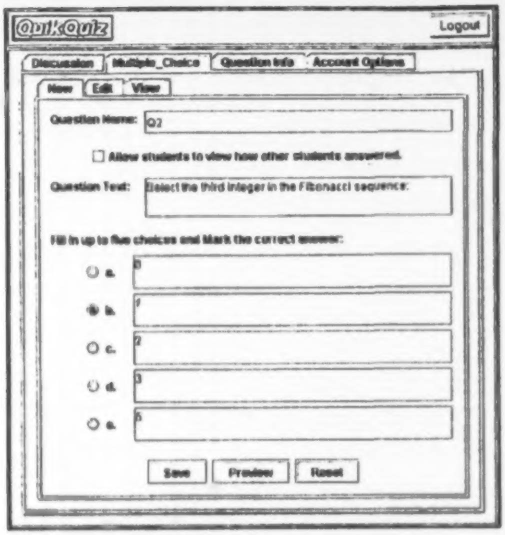
Many times an instructor in a face-to-face class asks questions of students to encourage interactivity and get a sense of learner comprehension. This is especially true in science and engineering courses. However, doing this at a distance is a special challenge. Such functionality is typically not available in current course tools. There are bulletin boards and quizzes, but they lack the informality that is crucial to the purpose of these techniques. These existing course tools also require the learner to go outside the content to answer the question, which is not desirable according to LaRose and Whitten (LaRose & Whitten 2000). To meet this need, we created a tool called "QuikQuiz"©, a simple quizzing tool that can be embedded in any html page and used either synchronously or asynchronously.

QuikQuiz© allows an instructor to ask either multiple-choice or discussion questions using Java applets. After submitting an answer to a question, the student sees the correct answer and may also see how other students responded up to that point. The instructor can review the responses at any time and has summarization/analysis tools to ease the task. The intent was to reduce, not increase, instructor workload.

Architecture

QuikQuiz© uses a client – server architecture and consists of two Java applications (the server) and four client Java applets: the CourseProducerClient, the InstructorClient, and two StudentClients. Server-side QuikQuiz© requires the installation of the Java 2 Platform, Standard Edition (SDK) version 1.3.1 or higher or the Java 2 Runtime Environment (JRE) version 1.3.x or higher. All the clients require the Java Plug-In 1.3 or higher. If either is not installed, the system automatically prompts for a download.

The SystemAdministratorClient allows the System/Network Administrator to create, view, and delete Course Producer accounts. This gives total control for administration of the network software. The CourseProducerClient allows one person to create and delete password-protected courses and assign them to individual instructors. Hence, one person coordinates the creation of courses but the instructor controls the content. This paper will focus on the InstructorClient and StudentClient functionality, since this represents the pedagogical aspects of the tool. Screenshots of both the instructor and student interface are shown in Figures 1 and 2 respectively.



Question Name: Q2

☐ Allow students to view how other students answered.

Question Text: Select the third integer in the Fibonacci sequence:

Fill in up to five choices and Mark the correct answer:

○ a. 0
● b. 1
○ c. 2
○ d. 3
○ e. 5

Question Name: Q2

Select the third integer in the Fibonacci sequence:

a. 0
b. 1
c. 2
d. 3
e. 5

Student1 (4/14/02 3:32 PM) : b.
Student2 (4/14/02 3:33 PM) : c.
Student3 (4/14/02 3:33 PM) : b.
Student4 (4/14/02 3:38 PM) : b.

Figure 2. Instructor's View of M-C Answers

Instructor's Functionality

The instructor can work with either discussion or multiple-choice questions. Each question type requires a question name and can be created, edited, deleted, and the individual responses viewed. The instructor also has the option of allowing students to see how other students have answered. In the example in Figure 1, the instructor created a multiple-choice question named QQ1. He /she entered the question and the available answers and also marked the correct answer. The responses to this question will be shared among students. Preview allows the instructor to see the question as seen by the student.

If the instructor clicked on View (Figure 2), she/he would see each student's response (i.e. which choice they selected), along with a time/date stamp. The individual response is color-coded red if incorrect and green if correct. A bar chart summary of all responses is also available. Since these responses are time dependent, meaning that the instructor sees all the responses up to the time the question was accessed from the server, an Update button was added to refresh the data. This allows the instructor to see any responses that may have just come in. If Print is selected, the combined responses are shown in an html window. The instructor can then save the printout using standard browser features. This was necessary because of the security features of Java.

A discussion question (Figure 3) is similar in creation, but differs in response display. The instructor names the question, selects sharing of answers, and enters the question as well as the answer text. A third box asks for answer keywords, separated by commas. This is used in the analysis of the responses, discussed shortly. If no entries are made in the keyword box, the instructor's answer is parsed to derive keywords.

When the instructor Views a discussion question (Figure 4), he/she sees the individual student responses with a date/time stamp. In addition, keywords contained in the students' response are highlighted in green and a summary statistic shows the percentage of keywords contained in that response. These techniques are intended to make analysis quicker and reduce workload without sacrificing accuracy. Update and Print are available, as described previously.

Question Name: Q2

Question: Define the Fibonacci Sequence

Answer: F0=0, F1=1 and every number thereafter is the sum of the previous two integers in the sequence.

(88.24%) peterj1 (4/28/02 5:39 PM) : F0=0, F1=1 and every number thereafter is the difference of the previous two numbers in the sequence

(100.00%) peterj2 (4/28/02 5:45 PM) : F0=0, F1=1 and every number thereafter is the sum of the previous two integers in the sequence

(5.88%) peterj3 (5/5/02 7:42 PM) : This is test response 3

Figure 4 Instructor's View of Discussion Answers

The Question Info tab depicted in Figures 1 and 3 accesses the entire set of discussion and multiple-choice questions for a course in the familiar directory tree structure. Instructors can open the folder for both question types and view/edit each question and response. Selecting a specific question displays the entire URL for that question. This can be copied and pasted into standard html to create the necessary links to make this work.

The Account Options panel allows the instructor to set preferences and options that affect the entire course, such as Change Password and Discussion Analysis. Change Password is a standard function, but Discussion Analysis relates to two utilities that require more description. In one utility the instructor can control the keyword-matching threshold. This threshold determines the highlight color of the summary statistic. The Minimum Keyword Length combo box specifies the length of words in the instructor answer that are used to generate keywords if they are not explicitly specified. For instance, if the "5 Characters" entry is selected, all words in the instructor answer that are 5 characters or more are used as keywords.

Student Functionality

A typical student screen for multiple-choice questions is shown in Figure 5. The student is asked to enter a name, which is used in stamping the responses. If the WebCT tool is used, there is a JavaScript that will interrogate the WebCT cookie and automatically insert the user's ID. This is instructor selectable. If privacy is an issue, especially for shared answers, the instructor could assign pseudonyms.

The student either types in their response to the discussion question or selects an answer from those available in the multiple-choice list. When the Submit is clicked, the answer is sent to the server and the instructor's response is displayed, along with the student's response. If shared answers are enabled, the Answers tab shown in Figure 6 is highlighted and students can see how other students have responded up to that point. We had considered an "Update" function for the students, but searching for previous responses increased the complexity beyond that desired. A student can always send in another response to see the newer submissions. This solution does increase the number of responses. A better solution is being worked on.

Figure 6 Student View of Discussion Answers

QuikQuiz© Use

At the outset, QuikQuiz© was intended to simulate the interaction of a face-to-face class, but in the asynchronous mode. The instructor could log in at any time and review students responses, save them, or print them as just described. The instructor could also send feedback to the student concerning misunderstanding of concepts, etc. This feedback is crucial for learning and the real reason for the tool, other than interaction.

However, we discovered another positive use of the tool. In all our courses we make use of the Rensselaer 80/20 model (Lister, et al 1999) that has both asynchronous (80%) and synchronous (20%) activities. There is nothing sacred about this distribution and it should be adjusted for instructor, student and content considerations. The important idea is that there *is* a synchronous component to every course, be it videoconferencing or simple text chat.

In a course called GUI Building, offered in the Fall of 2002, we would all meet in a chat room to discuss "administrivia" and answer student questions. Occasionally a guest would join us. Once these activities were completed, the students would adjourn to an on line module we called "Warm up". This module introduced the topic for the week and included a QuikQuiz©. It quickly became evident that if the students stayed in the chat room while doing this module, the instructor could monitor the student responses to the QuikQuiz© in almost real time. Since the chat facility allowed for private messages, the instructor could also give feedback to students immediately. Clarifying misconceptions as soon as possible makes this synchronous meeting much like a face-to-face course. In fact, it is even better because the feedback can be given privately and an exchange between student and instructor can be done without exposing the student to peer ridicule.

Using the Internet to Create an Integrated Thematic Unit Across the Curriculum

Terry H. Daniels
Department of Education
St. John's University
United States
crtstringer@pobox.com

Abstract: The problem as it exists in many K-12 classrooms is that computers are in place in schools but not being utilized to their full extent. It was noted that there was a need for a complete course on how to use computers in education rather than learning individual skills in isolation or a particular piece of software. The literature carried strategies for single unit themes, while teachers were asking to be shown multiple strategies. A course of study was developed at two institutes of higher education based upon what teacher-learners should take back to their classrooms. The course that evolved gave teacher-learners the means to use technology to increase access to information, use technology tools to improve communication, use technology tools to enhance reporting of information and use technology tools to more effectively collect, analyze and share data.

Introduction

Today's classroom teachers have the necessary technology in place but have limited skills to integrate instructional technology into their curriculum. "Teachers must be prepared to provide technology supported learning opportunities for their students," according to the National Education Technology Standards for Teachers (ISTE, 2002. p.4). Technology as a teaching tool is an essential skill that teachers should be required to learn and demonstrate competency in its use. A course of study was developed at New York Institute of Technology and St. John's University to prepare graduate education students to infuse technology into their curriculum. The methodology used was generic to all K-12 teachers and covered all curriculum disciplines. To meet the needs of graduate students, information and activities are presented that is relevant the needs of the learners. Inquiry-Based Learning (IBL) emphasizes research, critical thinking and multi-disciplined projects to achieve course outcomes. Students acquire problem-solving skills by developing a learning-centered curriculum. It is authentic learning by identifying real, current, important and practical problems that require a solution. Center to IBL are *Essential Questions* and *Tasks* that allow students to integrate technology into their research, ask meaningful questions, verify research, interpret their research and present it in a meaningful format. Use of the Internet is an essential element in producing the final product.

Discussion

Ely (1996) discusses a direction in education that requires teachers to become technology literate as set forth in 1989 by the U.S. Congress Office of Technology Assessment. Ely found that little had been accomplished in attaining this goal between 1989 and 1995. It is just the last few years that a concerted effort has been set forth led by the International Society for Technology in Education to make educations aware of the value of instructional technology. Tiene and Ingram (2001) emphasize that the World Wide Web contains a vast amount of educational material that today's teachers must learn how to properly convert information found on the Web into well-designed lesson plans. Berg (2002) questions the relationship of the amount of money being invested in technology the impact of teacher training, usage and productivity.

In today's classrooms students are becoming more Internet-savvy. The professors that are teaching these students are finding it more difficult to stay ahead of them (Moore & Engeldinger, 2001). According to Mabogo (2001) in a survey of 34,000 faculty members, only 35 percent reported using the Internet to conduct research, and 38 percent used technology to create class presentations. The National Education Association (NEA, 2001) has stated that technology is changing the classroom in the way faculty teach and how students learn. Administrators, staff and faculty need to understand the role of technology in the classroom and how it complements the educational experience. The International Society for Technology in Education (ISTE, 2000) stresses that it is essential for teachers to create a learning environment through the powerful uses of technology. Technology should not be taught in isolation but combined with traditional methodology to create new approaches to teaching curriculum while addressing individual needs.

Implementation

Ali and Elmahdi (2002) feel that it is difficult for senior teachers to change their teacher-based style of presenting a lesson and are reticent to embrace technology. It is therefore important when teaching technology to engage teacher-learners at all levels in meaningful hands on projects from the onset of instruction. Through the use of project-based building block constructivist methodology a course was designed that gave teacher learners new ideas to infuse technology into their curriculum while learning. The instructor, as required, could adjust the time spent on each module on a needs basis. The course consisted of 15, 2-hour sessions that permitted teacher learners sufficient time to work on projects and develop questions if any problems arose. The course consisted of eight learning objectives and a rubric for expected outcomes for each objective.

The eight learning objectives were as follows:

1. Teachers will be able to incorporate the use of e-mail into their professional lives. This was accomplished by sending a message to the instructor with a graphic attachment contained in a word processing document. Additionally each teacher-learner was required to exchange e-mail messages with their peers and instructor.
2. Teachers will be able to locate and identify five subject area curriculum-based Web sites on the Internet. They will also be able to evaluate and select appropriate technology for specific content areas relevant to their grade level. A brief paragraph was written about each site that included the URL of the site, together with contents that would be of interest to other subject area teachers.
3. Teachers will be able to integrate technology-based instruction and project-based ideas using information obtained from the Internet. Teacher learners were able to complete a distance education module by accessing BlackBoard (2000), the class Web site, to plan a trip to another state via automobile. They used hyperlinks to visit a trip-mapping site for driving instructions, maps, hotels and places of interest. A final report was filed via e mail with an attachment requiring editing and copy and paste to create a two-page report.
4. Teachers will be able to use Inspiration (2000) a semantic mapping program in a curriculum area to reduce complex information into small parts that can easily be understood and learned. Teacher-learners were able to design through visual mapping and/or worksheets classroom materials.
5. Teachers will be able to infuse technology into their curriculum. Teacher-learners were able to design an Inquiry-Based thematic unit that included a Scenario, Tasks, References, Product(s) and Assessment.
6. Teachers will be able to present subject area material using PowerPoint. Teacher-learners were able to present a slide show depicting subject area materials consisting of a constant theme. Storyboarding was used to layout the project.
7. Teachers will be able to incorporate EasyBook Deluxe (1997) into their curriculum. Teacher-learners created a book that consisted of a title page and a minimum of four pages of content using a constant theme predicated upon the level of the class and curriculum.

8. Teachers will be able to create a class or school home page using a Web authoring program. Teacher-learners created a home page consisting of three elements, 1) general interest, 2) graphics and 3) hyperlinks to two other pages fostering a constant theme.

Conclusions

The course of instruction was designed and developed for the implementation of a doctoral applied dissertation. The ideas and curriculum evolved over ten years of training preservice and inservice teachers at the master's level of instructional technology. Students' wants and needs aided in producing a product that can be implemented in the classroom as soon as the teacher-learner has mastered each objective.

There are many competent administrators and instructional technology professionals in place in the school system. What is questionable is how instructional technology is measured and who sets the standards, and are the policy makers knowledgeable enough to make these decisions. Sujo de Montes and Gonzales (2000) contend that while schools are acquiring technology, administrators are not directing sufficient funds into the development of competent technology-based teachers. Computers are in place but teachers don't have a solid instructional technology base from which to teach. Teachers are not adequately trained in the proper integration of technology into the curriculum. There is reluctance from older teachers to change their imbedded ways for fear of losing control of their classes to phobias about using computers. Newer teachers more readily embrace technology. A portion of teacher reluctance toward using instructional technology is availability of lab time and Internet accessibility in a continuous and long-term time frame. Hargrave and Hsu (2000) noted that most undergraduate preservice teacher programs offer one course in use of technology in the classroom. They contend that this single technology course will not adequately prepare future teachers in the infusion of technology into their classrooms. During a two-year study of integrating technology into higher education Vanatta and Beyerbach (2000) drew many conclusions:

1. Lack of interest and expertise among faculty.
2. Poor comfort level regarding planning educational technology activities.
3. Training should facilitate the planning and development of technology-rich lessons and activities.
4. Technology integration should be connected to "course content" objectivities and assignments.

Today's inservice and preservice teachers should be cognizant of the value of technology for research, problem solving and creative expression (Burns, 2002).

Applying Multi-Intelligent Adaptive Hypermedia to Online Learning

Benay Phyllis Dara-Abrams, Ph.D.
Information Systems
College of Professional Studies
University of San Francisco
and BrainJolt
United States
benay@dara-abrams.com

Abstract: While the Theory of Multiple Intelligences has been applied in classrooms, demonstrating that learners benefit from multiple entry points and multiple representations of material, this study examines whether the Theory of Multiple Intelligences can be applied to online learning. The study was conducted in three stages: user characterization, prototype development, and formative evaluation. Adaptive text presentation and adaptive multimedia presentation modify content based on a stereotype user model, characterizing users by technical background and most developed intelligences. Implementing Entry Point Framework and multiple representations, the prototype uses explanation and page variants for content adaptation. The formative evaluation indicates that further application of the Theory of Multiple Intelligences, Entry Point Framework, and multiple representations will improve the prototype, offering multi-intelligent content presentations, moving toward "anyone, anyhow" learning.

Introduction

Advances in adaptive hypermedia technology and Web-based asynchronous communication provide the technology foundation for online learning environments, which not only deliver content in a time- and distance-independent manner but which also adapt content according to a user model based on cognitive theory and educational methodology. This study addresses the research question: Can the cognitive Theory of Multiple Intelligences be used to support adaptation in an online learning environment?

The research is built on theories of cognition and learning, educational methodologies derived from these theories, and technologies to construct an artifact embodying these methodologies (Fig. 1). The technology foundation is based on user modeling and adaptation technologies in educational hypermedia (Brusilovsky 1998) as well as multimedia technologies and asynchronous, self-directed learning in Web-based environments (Harasim 1999). In addition, prior work in Intelligent Tutoring Systems (ITS) underlies the development of educational adaptive hypermedia applications (Goettl, Halff, Redfield, & Shute 1998).

The cognitive Theory of Multiple Intelligences (Gardner 1983/1993) and the learning theory of constructivism (Bruner 1986) form the theoretical foundation for the study (Fig. 1). The application of the Theory of Multiple Intelligences in classroom environments has demonstrated that individuals with varying sets of most developed intelligences benefit from the use of multiple entry points and multiple representations of material when learning new subject matter (Gardner 1999). The prototype developed for this study forms the basis for an "anyone, anyhow" approach to online learning, seeking to eliminate constraints due to varying development of intellectual faculties through the use of these educational methodologies.

Methodology

In order to answer the research question, the study was conducted in three parts:

1) Development of understanding goals and user characterization based on the three most developed multiple intelligences and technical background of each participant
2) Development of prototype learning framework and two prototype learning modules
3) Formative evaluation of multi-intelligent adaptive hypermedia learning modules

Through online questionnaires, participants were asked to provide data for the development of individual characteristics based on the three intelligences that appear to be the most developed in each individual. A user model was developed based on the most developed intelligences and technical background of each learner.

Learning outcomes were defined for learning modules on Legacy Systems Integration for technical participants and on an Overview of Web and Internet Technology for non-technical participants. The learning modules were then designed based on the understanding goals developed through the Teaching for Understanding Framework (Perkins 1998). Participants were asked to use the online learning modules through the Web-based multi-intelligent adaptive hypermedia learning framework and comment on their learning experience, providing feedback for the improvement of the prototype learning modules and framework.

Prototype Development

In designing the research study to answer the research question of whether the cognitive Theory of Multiple Intelligences can be used to support adaptation in an online learning environment, a prototype was designed for a multi-intelligent adaptive hypermedia learning environment (Fig.1). Two prototype learning modules were developed - one for a technical audience and one for a non-technical audience. In the formative evaluation stage of the research study, participants provided feedback on the prototype learning modules.

A stereotype user model was developed as a database containing the three most developed intelligences and the technical background of each participant. Content and link adaptation methods and techniques from adaptive hypermedia technology are used to deliver content. Through adaptive text presentation and adaptive multimedia presentation, the prototype employs attribute values in the user model to modify the content of the learning module pages so that the content presentations activate each user's three most developed intelligences. The method of explanation variants and the adaptive hypermedia technique of page variants provide support for multiple representations and different entry points, depending on user characteristics.

Formative Evaluation

The study focuses on online learning for an adult population, using research subjects 17 years of age and older. Of the 34 participants in the first stage of user characterization, 33 participants completed the study, using one of the learning modules and providing feedback on areas in which the prototype learning modules can be improved. The feedback received from participants is suggestive of the usefulness of applying the Theory of Multiple Intelligences to online learning. Based on participant feedback, the prototype can be improved by allowing for multiple levels of technical proficiency, adapting to the level of understanding by providing more explanations for novice users and more challenging content for advanced users. To address difficulties in determining the most developed intelligences, the prototype can be improved by making the user model adaptable, allowing users to examine and update their user attributes. This would allow the individual to serve as the authority rather than the questionnaires, as recommended by multiple intelligence theorists (Armstrong 1993/1999).

Participants, particularly those with well-developed Bodily-Kinesthetic Intelligence, requested more interaction and online testing. Other participants, particularly those with highly developed Naturalist Intelligence, suggested the use of metaphors in the presentations. Users, particularly those with well-developed Spatial or Musical Intelligence, found the animated graphical presentations helpful and suggested greater use of graphics, animation, and sound effects in the content presentations. In addition, overview information, upfront instructions, and examples were requested to help users achieve their understanding goals.

BEST COPY AVAILABLE

Assumptions and Limitations

Questionnaires were used to develop the user characterizations in terms of the three most developed intelligences. These self-report questionnaires make two assumptions:

1) Participants can answer questions with an understanding of their own skills
2) Answers can be used to determine a participant's three most developed intelligences.

The prototype learning modules incorporate only a small subset of the potential representations and entry points that can be used for explanation variants of the subject matter. A limitation of developing a multi-intelligent adaptive hypermedia schema is that each variant must be individually designed by a person knowledgeable in the subject matter, in the educational methodologies of multi-intelligent approaches, and in Web and hypermedia technologies. The prototype is necessarily a simplification of the design for fully multi-intelligent learning modules.

Significance of Study

Feedback from the formative evaluation indicates that improvements can be made to the learning modules and framework by increasing the use of the Entry Point Framework and multiple representations educational methodologies based on the Theory of Multiple Intelligences so that modules embody fully multi-intelligent approaches to content presentation. An affirmative answer to the research question and the instantiation of the Theory of Multiple Intelligences in the prototype user and adaptation models demonstrate the feasibility of building a personalized online learning environment that considers differences among individuals in thinking and learning. The prototype forms the basis for the development of an "anyone, anyhow" approach to online learning, with the study indicating improvements that can be made in the multi-intelligent adaptive hypermedia approach to increase accessibility to "anyone" through greater use of multi-intelligent "anyhow" approaches to content delivery.

Further Information and Demonstration

Prototype multi-intelligent online learning modules are available for demonstration and trial purposes at: http://www.brainjolt.com. Further information on the research study is also available on the website.

Concept Relationship Types for AHA! 2.0

Paul De Bra, Ad Aerts, Brendan Rousseau
Department of Computer Science
Eindhoven University of Technology (TU/e)
PO Box 513, Eindhoven, The Netherlands
{debra,wsinatma,broussea}@win.tue.nl

Abstract: In adaptive Web-based applications such as on-line course material, virtual museums and shopping sites, there are different types of relationships between objects, pages or high-level concepts. They indicate that some concept is a prerequisite for another concept, that a page or object exemplifies a concept, that a user reading a page gains knowledge of or shows interest in a concept, etc. In AHA! version 2.0 (De Bra,et al, 2002) such relationships are expressed at a very low level through adaptation rules. In this paper we show how to define higher level *concept relationship types* (such as prerequisites) and how to automatically translate instances of these types, called *concept relationships* to adaptation rules for AHA! This work is part of the Adaptive Hypermedia for All project of the NLnet Foundation.

Introduction

When the AHA! system was first built and used for an on-line course (on the subject of hypertext and hypermedia) the relationships between pages and concepts were simple: reading pages contributed knowledge about concepts, and knowledge about certain concepts was a prerequisite for reading other pages (or for the inclusion of fragments with additional explanations). See (De Bra & Calvi, 1998) for a description of an early version. AHA! version 1.0 introduced a bit, and version 2.0 a lot more possibilities for describing the interaction between pages and concepts. In (De Bra et al, 2002) we describe the powerful adaptation rule language used in AHA! 2.0 that lets authors specify how a rich user model should be updated using *condition-action rules*. Early comments we received on these new possibilities indicated that AHA! 2.0 offers what can best be described as an *assembly language for adaptation*. It became clear that higher-level descriptions of the relationships between concepts were necessary. In this paper we describe how the notion of *concept relationship types*, inherited from the AHAM reference model (De Bra et al, 1999), can be incorporated into the AHA! system. We first describe how to define a concept relationship type, using an XML notation that is similar to that of AHA! 2.0. We show how a simple drawing of concept relationship structures (possibly using different relationship types) can be translated automatically to the combined domain/adaptation model of AHA! 2.0. This idea has led to the development of a new authoring tool that aims to bring back to AHA! what was lost through the introduction of the *condition-action rule language*: ease of use for authors.

Defining and Using Concept Relationship Types

Concept relationships are a common notion in adaptive Web-based applications. They can be used to represent *prerequisites* in an adaptive course and to propagate *knowledge* from pages to sections and from sections to chapters. This is essentially how systems like Interbook work (Brusilovsky et al, 1998). In a museum there may be *exemplifies* relationships between paintings and a painting style or a *painted by* relationship between paintings and painters. In an on-line shop products may be *competing with* other products or may be *complementing* other products. The overview papers (Brusilovsky, 1996) and (Brusilovsky, 2001) show the ranges of applications in which adaptive hypermedia techniques are used. The AHA! system is not aimed at one specific application area, but tries to offer general-purpose functionality. It uses a combined domain/adaptation model to indicate how concepts relate to each other and how the system should update the *user model*. In (De Bra et al, 2002) the rule language of AHA! version 2.0 is explained in detail. A drawback of this approach is that *concept relationships* are described through their effect on the *user model* only. Not only are the adaptation rules difficult to write, in applications where different types of relationships play a role it is also difficult for authors to recognize which relationships are expressed by which adaptation rules. We therefore propose a new authoring tool that uses *concept relationship types* and that provides automatic translation from *concept relationships* of a defined type to AHA! adaptation rules. In the terminology of the AHAM reference model (De Bra et al, 1999) this means we create an (at least partial) separation between the *domain model* and the *adaptation model*.

We illustrate the use of concept relationship types through the examples of *prerequisite* and *knowledge propagation relationships*, as used in educational applications. The following figures could represent a few concepts in an imaginary course on Web concepts, how they contribute knowledge to the entire course topic, and how they "depend" on each other:

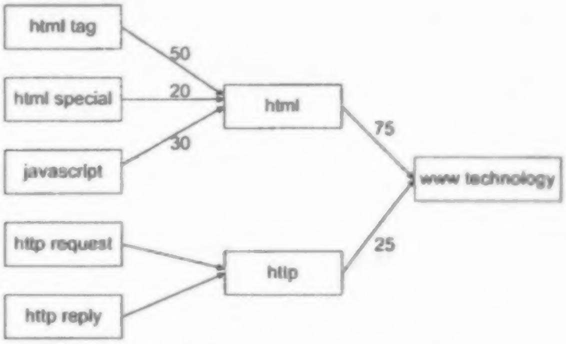

Figure 1: knowledge (update) structure in a course.

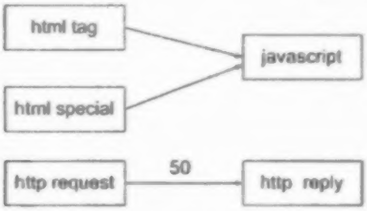

Figure 2: prerequisite relationships in a course.

From the graphs we observe the following properties of these concept relationship types:

- The relationships are all *binary*. We see that we can use two or more relationships with the same (source or) destination, to indicate that several pages contribute knowledge to a concept or that several pages are a prerequisite for a single concept. We shall see below how this affects the generation of the adaptation rules.
- The graphs are both *acyclic*. This may not be true for all imaginable relationship types. An authoring tool can verify whether the property holds, if needed.
- Relationships have an optional value associated with them. For the knowledge this indicates how much knowledge the source concept contributes to the destination. (In terms of a concept *hierarchy* this would be contribution of *child* concepts to *parent* concepts.) For the prerequisites it indicates how much knowledge of the source concept is required before the destination concept becomes "suitable".

In AHA! entering concept relationships becomes as simple as drawing a (labeled) graph. (We do not pretend that *designing* a proper structure of concept relationships is simple.) The new AHA! concept relationship authoring tool can show the graph for each concept relationship type separately or can overlay the graphs using different colors or line styles. Below we show two examples: the definition of *knowledge propagation* and the definition of the *prerequisite relationship type*.

In the first example we show (in a simplified way) how knowledge is propagated. (Note that another concept relationship type is needed to make a page access generate knowledge about a page. The example below only shows how knowledge is transferred from one concept to another.)

```
<concept_relation_type>
  <name>knowledge propagation</name>
  <color>blue</color> <style>full</style> <properties acyclic="true"/>
  <listitems>
    <generatelistItem location="source.knowledge" isPropagating="true">
      <requirement>true</requirement>
      <trueActions> <action combination="DIV_S">
        <concept>destination</concept>
        <attribute>knowledge</attribute>
        <expr>destination.knowledge + var:DIVIDE * _source.knowledge</expr>
      </action> </trueActions>
    </generatelistItem>
  </listitems>
</concept_relation_type>
```

Using this concept relationship type definition the authoring tool can translate the knowledge update edge between "javascript" and "html" (in Figure 1) to the following AHA! code:

```
<concept>
  <name>javascript</name>
  ...
  <attribute name="knowledge" type="true" isPersistent="true" System="false">
  ...
  <generatelistItem isPropagating="true">
    <requirement>true</requirement>
    <trueActions> <action>
      <concept>html</concept>
      <attribute>knowledge</attribute>
      <expr>html.knowledge + 0.3 * _javascript.knowledge</expr>
    </action> </trueActions>
    </generatelistItem>
  </attribute>
  ...
</concept >
```

This example shows the following elements in the translation:

- The generated adaptation rule belongs to the "knowledge" attribute of concept "javascript" (the source), so whenever this attribute value changes the rule is triggered. (This rule has no condition: the "requirement" is simply "true". The condition is translated as well, but here it is just trivial.)
- The action of this rule updates the "knowedge" attribute of the concept "html" (the destination). The *change* in the "knowledge" value of "javascript" is used. This is indicated by the prefix "_".
- When several knowledge propagation relationships have the same destination the fraction of the knowledge value change that is actually propagated is calculated by dividing 1.0 by the number of sources. However, in the example of "javascript" and "html" the divider that would be calculated by default is overridden by the label "30" in the graph. (Allowed because of "`var:DIVIDE`".) This results in the division factor 0.3. (For "http request" and "http reply" the factor is 0.5.) The term "`DIV_S`" indicates division by *source* of the relationship, "`DIV_D`" would mean division by *destination*.

```
<concept_relation_type>
  <name>prerequisite</name>
  <color>red</color> <style>full</style> <properties acyclic="true"/>
  <listitems>
    <generatelistItem location="destination.suitability">
      <requirement>true</requirement>
      <trueActions> <action combination="AND">
        <concept>destination</concept>
        <attribute>suitability</attribute>
        <expr>source.knowledge > var:70</expr>
      </action> </trueActions>
    </generatelistItem>
  </listitems>
</concept_relation_type>
```

The prerequisites "html tag" and "html special" of the concept "javascript" (in Figure 2) result in the following piece of AHA! code:

```
<concept>
  <name>javascript</name>
  ...
  <requirement>
    html_tag.knowledge > 70 && html_special > 70
  </requirement>
  ...
</concept>
```

This example shows the following elements in the translation:

- The prerequisites contribute to the "destination" concept (in this case "javascript").
- The "suitability" attribute mentioned in the rule is actually a pseudo-attribute. Using it in a concept relationship type means that it is the "requirement" of the whole concept that will be created.
- The "source.knowledge > var:70" expression means that the knowledge value of the source concept (html_tag or html_special) is compared with 70 or with a number given as label in the graph. (The real XML representation uses &gt; instead of > because of XML restrictions.)
- The "AND" combination of the action means that the expressions for different prerequisites are combined using the logical *and* operator (represented by && here). It means that all prerequisites for a concept must be satisfied in order for it to be considered suitable. (For other types of relationships the combination may also be "OR", meaning that at least one of the conditions must be satisfied. Combinations of requirements from relationships of different types, having the same destination, are always combined with "AND" (and thus not explicitly written in the definitions).

Conclusions and Future Work

In this paper we have shown how drawings of concept relationships can be translated to AHA! 2.0 concept and adaptation structures. In order to do so an AHA!-like syntax was developed to define concept relationship types and their translation to adaptation rules.

The translation of concept relationships to AHA! is fairly straightforward, even in the presence of relationships of several different types in the same application. A prototype interface enables authors to create concept relationships and have them translated to AHA!. It contains the definition of a number of commonly used relationship types. In the future we will also develop an interface for defining new types and add the ability to author adaptation rules at the presented high level and the low level of AHA! 2.0 at the same time.

Adaptation of the e-learning web application "Campus Virtual Teledomedia" to obtain an open and accessible information management system

Antonio de Castro Orbea, Cristobal Romero, Carlos de Castro
Departamento de Informatica y Análisis Numérico, Universidad de Cordoba
14071 Campus de Rabanales, Cordoba, España
cdecastro@uco.es

Abstract: In this paper we describe our project of transformation from an elearning web application in stage of production to an open and accessible management information system capable of provide an individualized user experience to overcome a physical or psychological disability from the user and access a common background or particular information source. New features will be added to the system like local domotics system control, cognitive rehabilitation programs or task scheduling support.

Introduction

The last 10 years have witnessed an explosive growth of the new technologies of information through the integration of telecommunication networks with multimedia capabilities. These technologies offer new ways of communication useful in business or private areas. There is no doubt that social relationships are evolving towards a social model based in the interchange of multimedia information. However, there are 37 million people with disabilities in the EU, while the number of older Europeans is steadily increasing. These groups of risk face to severe social exclusion due to a range of technical barriers when using the Internet, specially Web-based services. All citizens have the right to use all benefit from new opportunities that the Information Society offers. People with disabilities and older persons experience sometimes difficulties to access these new technologies and services, as some barriers can be inadvertently created by the Information Society itself. On the other hand Information Technologies and Services can greatly help to overcome other environmental or social barriers, encountered by people with disabilities and older persons.

Our project (in a initial stage of development) tries to provide an elearning web-based site specially oriented to people with a wide spectrum of disabilities or elderly people, guaranteeing a full access to educational programs, rehabilitation programs, collaborative environments or a multimedia contact-center.

Individualized user experience

Due to specials needs of the kind of user that this application aims to, it is necessary to design a full set of mechanisms to provide an individualized user experience, according to their disabilities and interests. It would be possible to access individualized web contents or integrate a full set of interaction devices with the web application, such as properly designed wheelchairs, adaptive switches to control devices, or speech synthesizers.

The project expects the adaptation of a CMS (contents management system) and an e-learning system called "Campus Virtual Teledomedia". This application is already in a production stage, though it has some accessibility limitations. It is necessary to take a "design for all" philosophy in order to improve the accessibility of disabled or older people and obtain a system capable of an automatic adaptation to special needs or desabilities of the user. Besides this goal another objective of the project is to take a flexible and modular development strategy to make new functionalities possible, such collaborative environments, task scheduling support, local domotics systems management or cognitive rehabilitation process.

The main feature of the proposed system is the modular and multi-layer architecture to achieve the independence between information (stored in a neutral format based in XML) and the visual or sonorous specific format. The adoption of international or "de facto" standards like Web Accessibility Initiative (WAI) or Web Accesibility

Guidelines (WCAG) for the design of accessible web-bases services will guarantee the full compability with specialized presentation devices such as screen-readers or a tactil screen.

Besides this accessible feature new automatics transformation mechanisms will be designed to increase visual or sonorous aspects of the information showed to the user or simplify it to mere pictographic symbols (in situations of severe cognitive disabilities)

Main goals

- Facilitate a full access to the educational programs of the system, guaranteeing an individualized learning process and the remote tracking of the user progress
- Manage a home domotic network via an accessible web-based interface to achieve an increasing of the home security of the disabled or elderly user.
- Facilitate an immediate multimedia connection with an welfare remote center
- Provide support decision-making software to help the user to schedule or remind events or consult step-by-step guides of everyday activities.
- Provide a set of adaptable dynamic games useful for cognitive rehabilitation under the remote supervision of a qualified therapist.

Conclusions

The achievement of the presented objectives will suppose the transformation of an elearning application into an accessible information management platform open to future adaptations or devices, fully oriented to guarantee accessible and individualized learning or rehabilitation experience.

Modeling the Tutor-Learner Interaction in an E-Learning Environment: An Instructional Design Perspective

Abstract
Importance of modeling the rapport between tutor and learners in an e-learning environment arises from a learner-centered design approach in which it is essential for the designer to plan the support for learners. This paper describes the implementation of a graphical knowledge modeling approach developed at LICEF Research Center to orchestrate the processes and resources of tutors and learners. Organized into strata, the model allows representing the various roles of the tutor in an e-learning environment. Advantages of this approach include a filtering mechanism to facilitate management of complex interactions between tutor and learners.

Context

From a learner-centered approach in an e-learning environment, the tutor is an actor that supports the learner by addressing his needs with a variety of instructional strategies and tools. Several studies have contributed to understand the roles of the tutor (Goodyear et al. 2000; Rigault et al.1998; Rowntree 1995) as well as the nature of the support that can be provided to the learner (Harley et al. 2001). One of the key roles of the tutor in an e-learning environment is that the facilitator provides ample opportunities for interaction (Vrasidas 2000). According to Moore (1989), the tutor delivers instruction, gives lectures, provides feedback and encourages the learner, whilst the learner asks questions, submits homework and discusses problems. In an e-learning environment, this interaction cannot be completed without considering that, according to the learner's needs, the tutor can be called to assist the learner in other types of interactions: learner-content, learner-learner and learner-interface (De la Teja 1997; Hillman et al. 1994).

Given the complexity of the T-L interaction, the development of specifications to ensure the quality of the support provided to the learner can become an intricate task for the instructional designer who needs to plan and describe the actions, resources and conditions of the interaction. How is this to be done? It has been suggested that the use of models can be helpful to reduce complexity by separating out a small number of important things to deal with at a time (Rumbaugh et al. 1991). Of particular interest are models using a graphical representation language because they facilitate the elaboration of complex systems (Yourdon 1989; Scheiber 1993; Paquette 2002.) This paper depicts the use of a graphical modeling approach to represent the interaction between the learners' needs and tutor support. Two particular areas of inquiry are addressed: Which are the elements to consider when planning the support in an e-learning environment? How can the support provided by tutors be represented in a graphical form?

This paper focuses on the use of models in instructional design and presents the main characteristics of MOT Plus, the software used to model the Tutor-learner interaction. Finally, issues on the implementation of the modeling approach are addressed.

Instructional design and models

Since the early 1980's considerable work has been done on the use of models in instructional design (Romiszowski 1981; Wilson, Jonassen & Cole, 1993; Paquette 1994; Wasson & Bourdeau 1998). More particularly, studies done at LICEF[1] Research Center of the Télé-université, have led to the development of an instructional design method based on knowledge modeling. This method, known as MISA[2] describes in detail the process to elaborate the learner's model (Paquette et al. 2002), but information on how to model the support provided by tutors is scarce. To address this gap, this study examines how the different roles played by the tutor can be graphically represented in regard to the learner's model.

In MISA, the modeling approach rests on four main categories of knowledge: procedures, concepts and principles (Anderson 1983; Romiszowski 1981).

- Procedures are used to describe actions (e.g. Elaborate a definition of freedom).
- Concepts are used to represent the resources required to execute the actions (e.g. Forum, Online teaching guide) as well as the resulting product (e.g. Definition of freedom).
- Principles characterize the relationships between concepts and procedures (e.g. criteria to decide when or why certain choices should be made while using a procedure or a concept).
- Facts are objects, events, names, etc. (e.g Forum of course BIO 3059, a specific Web site).

MOT Plus

Different software tools are available to the instructional designer to create graphical models (Kasowitz 1998), but few of them allow visualizing the relationship of the four rather abstract knowledge units described above. MOT (French acronym for Object Modeling Tool) is the product of research and development efforts to answer that need. Fig. 1 presents the forms and links used to construct models with MOT.

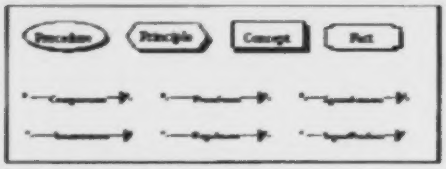

Figure 1. Graphical forms and links used in MOT and MOT Plus software.

Several researches in different domains (e.g. Paquette et al. 2001; Saliha-Hassane et al. 2000, De la Teja et al. 1997) suggest that these forms and links are enough to represent simple learner-tutor interactions. However, a more sophisticated tool was necessary to manage complex instructional scenarios in which, for example, the support provided by the tutor is varied and is expressed through different roles. A new version of MOT, i.e.MOT Plus, was developed to represent strata, a sort of organizing hierarchy. With strata it was possible to size the entire model in all its complexity but at the same time simplify the model description by separately representing specific points of view.

Modeling the T-L interaction

In exploring the advantages of MOT Plus in modeling the T-L interaction, the learner's model and the support provided by the tutor were represented in a large number of actions then divided up into specific tasks that would be handled by different roles. A filter mechanism was used to visualize only those graphical forms pertaining to a specific role. Furthermore, it was possible to keep the link between the different roles. Fig. 2 illustrates the main forms used in the elaboration of a model of the T-L interaction.

Figure 2. Forms used in the construction of a model of the T-L interaction.

With these forms, the different elements of the T-L interactions were captured. As shown in Fig. 3, the elements in the upper dotted box correspond to the learner's model. Here, the learner's action (main oval) consists in defining the concept of Freedom as stated in the objective of a learning unit (white rectangle). To accomplish the action, the learner is provided with different resources (gray rectangles): a forum and a bibliography. The definition of Freedom is the result (white box) of a learning effort done according to the rule (white hexagon) requiring that the action is accomplished in collaboration.

Figure 4. Partial view of the tutor's model.

In this model, the tutor assists the learner in the elaboration of a definition. He executes this process (oval) through a forum (gray rectangle), following the guidelines for online teaching (hexagon) that can be found at a specific web site. The main process is decomposed in two actions (dotted ovals) executed by the tutor according to specific roles: assessor and counselor (Goodyear et al. 2000). Details on the model can be fully specified indicating the tools, conditions, inputs and outputs for each one of the actions.

Conclusions

Depending on the complexity of the learning scenario prepared by the instructional designer, the model of the T-L interaction may require to be handled with filters and strata. The description of these functionalities goes beyond the goal of this paper. For the purposes of this study, it is important to highlight that modeling the T-L interaction reveals to be a complex endeavor due to the many roles and tasks of the actors. The type of support provided by the tutor as well as the resources he/she requires depend on the nature of the learner's needs, which are "construed" and difficult to predict (Vrasidas 2000). The present study suggests that MOT Plus is a useful tool to create a generic model where more specific instantiations can be integrated without creating communication overhead. The graphical modeling approach has increased the degree of completeness and coherence within and across the models of the two actors.

There are many factors that influence the interaction between the learner' needs and the tutor supported plans by the instructional designer. Further studies might include intervention of peers, experts, groups of tutors as well as the type of need as expressed by the learner (implicitly or explicitly). Moreover, the impact of innovative multimedia resources should be explored to develop more effective learner and tutor support.

GWeb Enterprise Portal

ABSTRACT

The George Washington University has developed an enterprise portal solution to fulfill the varied needs of students, faculty, alumni, staff and friends. The ability to integrate email, online student registration, courseware software, enterprise data and other existing resources into a comprehensive single-sign-on portal allowed for greater application interoperability, extended usage, and enhanced University wide communication.

PAPER

In late 1998, The George Washington University (GW) started conceptualizing innovative ways to use web technologies to replicate its sense of community in the online world and to enable more agile communication within its constituencies. GW needed an all-in-one comprehensive and integrated enterprise portal; a solution that would allow all types of constituents – students, alumni, faculty, staff or some combination of these roles - the ability to use services and receive information tailored to their specific needs. Moreover, the system was to provide the ability to integrate applications such as email, online student registration, courseware development and management, and other existing resources into a comprehensive single-sign-on portal.

GW decided to build its own portal and named it GWeb. The Interactive Multimedia Applications Groups (IMAG), a team within the Administrative Applications department of GW's Information Systems and Services, spearheaded the development of GWeb. Initial features were based on student, staff, faculty, and alumni interests, focus groups, GW administrative guidance, including the Web Advisory Committee of GW's Information Technology Advisory Council and the Technology Committee of GW's Board of Trustees. GWeb went officially live in September 2001 after a "test drive" period that lasted eight months, as we collected and responded to user feedback to improve services and features.

Developing the University portal independently allowed GW to focus on its specific needs and opportunities distinctive to GW. While the challenge of building a portal may have been greater than using a generic product, the autonomy and independence generated allowed GW to provide solutions responsive to the community's needs and values. Furthermore, the ability to integrate existing resources into a comprehensive single-sign-on portal allowed for greater application interoperability, extended usage, and enhanced University-wide communication.

The GWeb portal is based upon a mix of academic, collaborative, informative and personal services to encourage use and promote community interaction. Services of personal nature, such as weather from around the globe, movie show time listings, comics, and classified ads provide resources that would otherwise require users to search elsewhere for these features. The aggregation of the GWeb services increased usage and the effectiveness of communication between the University and its constituencies.

Today, thanks to its proven infrastructure, more and more applications are being built on top of the GWeb architecture to facilitate the University's operations and academic learning.

Currently, GWeb includes the following features:

- Role-based configuration. Users are presented with applications and communication that are relevant to their affiliation within the University (i.e. student, staff, faculty, alumni, or guest).
-
- Role-based polling and surveys. Users are presented with polls and surveys that are relevant to their affiliation within the University.
- Content management and distribution. Organizations and departments within the University can post news and events on the portal and have the same content syndicated out to their own website on the University's main web server.
- Online directory: Users can search email and campus addresses for faculty and staff. Student and alumni email addresses may also be searched.
- Access to external applications. The portal provides single sign-on to Email, library catalogues, and the University's online courseware application.
- Secure distribution: Staff and faculty can obtain instant, secure access to their personal identification numbers (PINs) for accessing BANNER, the University's enterprise system, over the web.
- Employment listings and employment applications: This application allows users to browse and apply online for GW employment opportunities. The data feeds directly from the BANNER database.
- Training registration: Allows training providers to manage GW employee training.. The system feeds data back to the BANNER system to record, track and report on fulfilled employee-training requirements.
- Bookmarks and Web Notes. Users can bookmark web sites or save the contents of various web pages through GWeb. These bookmarks and notes can then be shared with other GWeb users and accessed from any computer.
- Instant Messaging: Users can send instant messages within the GW network and to other popular networks, including AOL, MSN, Yahoo and ICQ.
- Alumni Mentoring Program: Students may browse through alumni profiles to select a mentor.
- Student Elections: Students may vote online for their school board representatives.
- Entertainment: GWeb modules include news from washingtopost.com, weather from around the world, comics, horoscopes, movie show time listings, live broadcasts of GW's radio station, real-time robotic cameras from around campus, news feeds from and classified ads.

Developing the portal required three predominant types of activities occurring almost concurrently: business development, technical development, and design and usability. Each is outlined below:

Business Development

It was necessary to build relationships throughout the University and beyond to make GWeb happen. Two types of relationships were required. First, relationships needed to be established within the University to secure commitment to GWeb. Second, relationships with content providers were required to enable GW to provide services such as news and movie listings. GW established a partnership with the Washington Post that became a win-win solution. While integrating washingtonpost.com with the portal, the Post developed the standards for content distributions, which will later be used with other washingtonpost.com customers.

Technical Development

GW's in-house knowledge of the systems that were to be integrated was one of the reasons for the successful design of the portal solution. IMAG's ability to easily reach for knowledge and expertise within the Administrative Application division made the links between the portal, the administrative data and the systems relatively simple.

Scalability issues were addressed carefully to ensure GWeb's ability to handle a growing user base and an expanded service offering. Furthermore, the University's high standard of and commitment to security demanded particular attention to preserving the integrity of University data.

Design and Usability

Crucial to the success and adoption of GWeb was making it easy to use and understandable for the user. Early on, mock-ups were created and their practicability examined. Special efforts went into creating an environment that would be friendly, inviting, and intuitive. Focus groups were used to assess ease of use, intended audience and future development needs. The personalization aspect of GWeb allowed for each user to see a specific page made especially for them. Whether the feature being used is a particular discussion group, a favorite news section, or weather reports from a hometown region, each user can easily personalize GWeb to their needs and preferences. Additionally, applications like email, instant messaging, and the courseware application are made accessible without additional logins.

The evidence of the success of the GWeb portal comes from the usage that we are registering. Whether because of the email integration, the instant messaging, or the comics column, users are valuing the application and are using it every day. Because of its successful adoption, the University has used the portal as one of the major means of communication. Surveys are proposed to users over the portal. The ability to then correlate the survey data with enterprise data provides the University with a powerful tool for strategic planning initiatives.

The self-service aspect of the portal has reduced the cost associated with providing direct assistance. The portal has eliminated the need for publishing a hardcopy version of the GW phone directory and reduced the costs associated with maintaining directory entries.

The portal has assisted with identification of data quality issues in our enterprise database. A few staff and faculty members who tried accessing one of the portal applications, which required the submission of personal data, learned that their birthdate or social security number was recorded incorrectly in the enterprise database and then were able to take steps to correct their information. Staff and faculty members can easily view their online directory entry and update it with a few clicks.

The employment vacancies listing program allows for the display of job descriptions, which were previously not available through the web. Job applicants can submit their resume online, thereby improving the quality of staff by increasing the pool of resumes from which University managers can choose.

There are several elements which give GWeb sustainability throughout the University. Its capabilities have changed the way we develop and deploy applications. For example, by being able to access our enterprise database, users are now able to provide correct and updated information ranging from birth dates to office phone numbers with only a few clicks. With our online directory, finding a department contact number or email address is simple. With the new calendar, users are able to add events into one consolidated calendar, which can be sorted by various user groups such as student organizations, classes, departments.

GWeb Portal has been well received throughout the GW community and has received support from Vice Presidents and the Board of Trustees, as well as becoming a permanently bookmarked site for thousands of students, faculty, administrators, and staff that populate the GW community. All these elements further sustain the University by providing information in a single consolidated portal, accessible to anyone, customizable by any user, and further projects The George Washington University's online presence in the world wide web.

Although GWeb has been live since September 2001, it is a work in progress. We have already added new features such as a robotic camera that allows the user to control viewing of various parts of the GW community. With such innovative modules being developed every day, GWeb has become a powerful tool and resource that will further sustain access to services and communication among the many constituencies that make up the GW community.

The fact that thousands of University constituents have incorporated use of the portal into their daily use of on-line services speaks for itself. An integrated tool such as this is the direction of the future for access to services and information. The business process, technical and usability challenges already identified and solved during this project should prove beneficial to any other higher education institution wishing to take the next step into the future of web-based services, integrated information and targeted communications.

Issues in Rural Uptake of Online Learning: an Australian Perspective

Dr. Ann Deden
a.deden@ecu.edu.au
Learning and Development Services
Edith Cowan University
Perth, Western Australia

Abstract: Worldwide, many hopes for improved access to tertiary education have been pinned on Internet-based telecommunications. This presentation reports the extent and success of attempts to encourage rural and remote Australian secondary school students to use the Internet to participate in tertiary education, and identifies key features of successful programs.

The Discrepancy Between Metropolitan And Rural Rates Of Tertiary Participation

Based on 1996 census data, the Australian Department of Education, Training and Youth Affairs (DETYA)[1] calculated that 28.4 percent of metropolitan Australians between the ages of 19 and 21 were enrolled in higher education, as compared with 18.3 per cent of their peers from rural and isolated locations. Yet rural Australians constitute 46 percent of the total population. In rural and especially in remote areas, populations tend to be very sparse, spread over vast distances. Transportation and communication are often minimal and seasonally unreliable. And a significant proportion of rural and remote Australians are disadvantaged not only by location but by socioeconomic status as well. Taken together, these factors make the issue of rural and remote education equity a challenge of daunting proportions. Many state and national government leaders expect that online learning offers a panacea that will happily resolve this dilemma.

The presentation reports the results of an investigation into whether this expectation is likely to be realised with current approaches, and derives a criterion list of potential success factors that should be piloted.

Project description

The investigation took the form of a structured survey of existing programs, and an analysis of those programs in terms of factors identified in the research literature as affecting secondary students' tertiary education decisions. We assessed the extent and methods used to address both factors that encourage tertiary participation and those that discourage it.

Most programs that met the criteria for inclusion is this study are limited to vocationally oriented in-School offerings, known as VET in School programs. Typically, these programs focus primarily on encouraging students to complete school through Year 12 by providing local access to an expanded range of attractive vocational subjects. Many such programs offer TAFE Certificate I or II qualifications, along with high school completion awards.

Programs such as the Nhulunbuy High School, New South Wales Access Clusters, and the New England Institute of TAFE programs integrate significant participation by the local secondary school, relevant local industries, community telecentres[2] and TAFE institutions. By engaging active local business and community support, the programs help create a climate in which further education, as well as the use of distance learning technologies, can become normative, and reinforced by social interaction. Furthermore, they demonstrate the relevance of advanced learning to careers in local industries. This shows students that they will not necessarily have to abandon their communities if they pursue tertiary goals. Experiences with supportive distance learning facilities and staff can also help secondary students feel more comfortable with the idea of engaging in tertiary study via distributed learning approaches.

---

[1] Name changed in 2002 to: Department of Education, Science, and Training (DEST)

[2] Telecentres are community-managed facilities that offer Internet access and skills training. Many also support video-based lectures and student assessment for tertiary vocational programs.

It was extremely rare to find university-initiated rural tertiary participation programs using technology. A number of universities, particularly those with regional campuses, conduct at least some rural student recruitment programs. However, there is at present no university program that uses online learning as part of a program guiding rural and remote Australian students through either an enriched conventional or an alternative pathway to university.

Edith Cowan University's Harvey Aspirations program is in the early days of a three-year pilot trial, seeking to adapt the Upward Bound model from the U.S. to Western Australian requirements, and to incorporate online learning as part of the process. While Aspirations provides more of the elements that the research suggests are essential for the success of tertiary encouragement programs, it continues to rely on a substantial amount of face-to-face contact, and as yet makes little use of the Internet. ECU is able to provide that at Harvey due to the proximity of its Bunbury campus. Thus, we were unable to identify any working model of a rural/remote tertiary encouragement program in which a metropolitan university campus provides the university component and uses distributed learning technologies to support any significant portion of its interaction and contact with distant school students.

However, from the analysed programs and related research, it was possible to generate at least a starting set of recommended features that would contribute to the effectiveness of any tertiary encouragement programs that used distributed learning technologies to reach rural and remote secondary students.

Toward a Best Practice Model

To be successful, model programs will need to effectively address as many of the factors that currently discourage country students from pursuing further tertiary learning, as well as incorporate a number of strongly encouraging elements (James et al. *op. cit.* 1999). Based on analysis of the data gathered, the following features can contribute strongly to the potential success of tertiary encouragement programs for rural and remote Australian students:

- Early intervention, perhaps as early as Year 7 and certainly by year 9 or 10, to help ensure secondary completion to a level appropriate for each students' tertiary study goals, to broaden students' exposure to career and related study options, and to begin to address any academic deficits or enrichment needs

- Inclusion of self-management and independent learning and living skills, including the use of distributed learning technologies

- Effectively addressing students' and families' financial concerns regarding the costs of leaving home for tertiary study

- Engagement of family, school and community members, and of local telecommunications resources, so that students experience more social support and continuity between home and away tertiary locales

- Focus on tertiary study pathways to careers that require university as well as TAFE preparation

- Active, well-integrated partnerships across participating educational sectors

- Community and family involvement in selection of subjects and provision of relevant work experience and work-based learning

- Residential camp experiences conducted on university campuses

- Incorporation of regional clusters of schools interested in the same program, with shared contribution to program teaching

- Use of distance learning and telecommunications technologies to foster ongoing high levels of interaction among cluster schools and with linked universities

- Technical and curricular support from state education agencies

- Active involvement with a specific university and/or faculty that offers courses seen as relevant and beneficial to the economic life of the community—whether it is geographically close or not

- Exploration of careers requiring tertiary preparation

- Tertiary level learning skills and academic remediation, bridging, and enhancement as appropriate to each student's goals and skill levels

- Provision of additional social, counselling, and academic skills support once students embark upon tertiary study

It is likely that such programs will also need to encompass some professional development for both secondary and tertiary teaching, counselling and advising staff. Significant professional and organisational learning will be involved as staff from different institutions and sectors work together to develop well-articulated pathways for rural and remote students, to track student progress, and to provide appropriate and effective programs and advice, both face-to-face and via distributed learning modes.

Next Steps

The findings of this study can help to guide strategic planning for tertiary access in any country facing the challenges of distance, culture, and socioeconomic status in its attempts to upgrade the educational attainment of its rural and remote citizens. The full government-sponsored report (to be published this year) includes a number of recommendations that will be considered at the national level, including the funding of pilot project designed to develop varied working best practice models.

Abstract: Universities worldwide are faced with enormous challenges as they decide on how the rapid changes in technology and the widespread availability of the Internet will impact upon their modes of operation. This paper examines the strategic planning implications of cost, risk, quality, and potential outcomes driving universities' investments in online learning. It explores a continuum of valid strategic positions universities can adopt, based on their analysis of these factors.

Universities attracted to Web-based delivery need well-defined policies and strategies in place that will give the them the best chance of promoting effective learning, gaining market share, generating profits, and demonstrating leadership in the quality of the online learning experiences they offer. In order to achieve such ends, a university must partner strategically, build its capacity wisely, and manage its online business commercially.

What Options Does A University Have In Defining Its Online Profile?

Every university needs to make a choice among 'big picture' strategy alternatives. For example, five possible options are suggested below, ranging from simple Web-assisted learning (effectively opting out of the competition) to one requiring a significant university commitment to Web-based delivery. In Australia, the national government's Department of Education, Science and Training (DEST) definitions of mode levels A, B, and C indicate the degree of Web-dependence a course displays. They do not and should not be taken to indicate that, for instance, Mode C is necessarily best in all circumstances. Rather, the choice of mode should be seen as reflective of the university's strategic market focus and pedagogical philosophy.

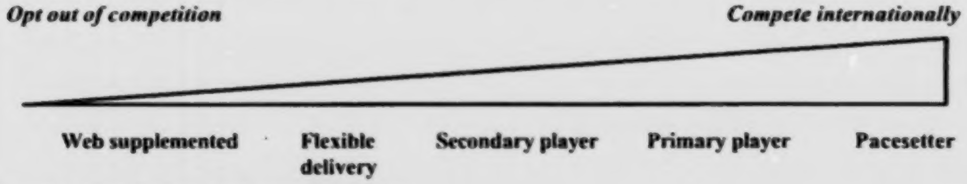

Figure 1: Continuum of online profile options

Option 1: Web-supplemented (DEST Mode A)

This option uses Web components to enrich the learning of a student cohort that is primarily campus and classroom based. Web use is recommended by the teacher, but is not strictly required in order for students to achieve unit outcomes. Universities may opt to offer this level of Web enhancement for some or all of its courses as a result of any of the following considerations:

- The course content is primarily hands-on laboratory or technical work.
- Students are unlikely to have good online access.
- The institution has decided to very gradually use the Web as one way to enrich the high-quality face to face learning experience that is already a distinguishing, marketable feature of the university.
- The particular course caters for only a small, local student population, and that population finds it relatively easy to attend regularly scheduled classes.

Online resources provided at this level can range from basic unit information to inclusion of other resources such as access to databases, and other topically relevant Websites, links to the university library and other student services. Given the traditional emphasis on on-campus teaching, it is likely that a university will find the largest number of its online learning resources and units will be at this level. Some institutions also start their online endeavours at this level. Though this is changing as student expectations rise, many courses marketed as 'online' have been primarily delivered via traditional print distance education.

Funding implications: Costs depend on features that are included and the condition of pre-existing course and unit resources. Average costs would range from a minimum of $500 to $5000 for the development of the materials.[1]

Option 2: Flexible Delivery using Web-dependent Units (DEST Mode B)

At this level, Web use is required, but other learning resources and/or experiences are also essential unit components. The Flexible Delivery option packages a mix of learning resources to support substantially online unit delivery. At this level, units and courses usually need at least moderate redesign to take advantage of Web affordances to create a more learner-centred environment. Hence, instructional designers, multimedia and Web-production personnel are typically involved. If this is the teacher's first foray at this level, then supportive professional development is also essential.

Universities may opt to offer this level of online engagement for some or all of its courses as a result ofany of the following considerations:

- It can enhance quality assurance for offshore programs.
- It aligns with the needs of an older local student population with work and home commitments that make traditional university attendance problematic.
- Students can be expected to have good online access.
- The university's IT infrastructure can provide reliable, reasonably high-speed access to remote learners, and to at least the library.
- The university has made a strategic commitment to using the Web to create more learner-centred teaching, and has aligned the necessary financial resources and support services.

Funding implications: Bates (2000) estimates costs for the development of a Web-based new unit to be around $28,300 Canadian dollars. Any such figure is simply an estimate. Bates gives four ways to estimate: 'wild guesses', 'marginal costs', 'careful estimates' and 'actual costs.' Multiplying such a figure by the number of units to estimate the cost of whole courses denies the possibility of economies of scale with template developments and other savings. The figure is also rubbery because the total cost will depend on the nature of the unit itself, and the tasks and resources that need to be produced.

Option 3: Secondary Player

---

[1] Unless otherwise stated, all dollar values are given in Australian dollars. With the exchange rate typical in mid-2002, the Australian dollar is worth a little more than half a US dollar.

A Secondary Player profile would involve offering Mode B or Mode C (fully online) units and courses. The critical feature here is the use of external providers (e.g., Open Learning Australia or OLA) for course management and marketing, in return for a percentage of enrolment income.

Universities may choose this approach for some or all of their online courses. For example, Curtin University of Technology offers most of its online courses through OLA, but also administers some directly. The decision to go to the market through a large broker or distributor can be influenced by factors such as:

- A determination that at least some programs can reach larger markets.
- The costs of reaching that wider audience are shared through a consortium approach.
- An opportunity to join with a larger provider that offers the IT infrastructure and support, and perhaps administrative support as well, that would be too costly for the individual university.
- A desire to enhance the university's name recognition through association with more widely known consortium members.

Funding implications: Funding implications will depend on the nature of the relationship, for example, whether the outside provider pays the university for unit development, or whether the university underwrites and contributes units. Administration, infrastructure and maintenance costs would need to be covered. However, the cost of joining a consortium can be significant.

Option 4: Primary Player

A primary player provides a fully e-commerce-enabled, e-learning Web Portal for all student-university interactions; may host secondary players' courses in non-competing areas; and markets through direct channels (e.g., Website, direct mail, advertising) as well as indirect channels (e.g., brokers, links to consortia and other accrediting universities).

Universities can reasonably consider this option when, for example:

- Their IT infrastructure and administrative systems are all integrated, online, robust on a 24x7 basis, and secure, allowing for all student transactions and services, as well as units, to be delivered entirely via the Web.
- They have identified programs with strong actual or potential online learning markets. These markets offer enough income to cover not only course development, delivery, and upgrading but also marketing and at least a portion of significant ongoing IT infrastructure and administrative system improvements.
- They have developed and debugged the online courses for these markets.
- They have strong name recognition in their selected market segments, and have experienced success in marketing their online courses.
- They have developed and implemented policies and practices that assure quality staffing, quick response times from teaching and support staff, and reasonable workload formulas for delivering online courses that will meet the quality standards of their face-to-face programs.
- They have made the financial commitment to continued updating and enhancement of all of the above.

Funding implications: Infrastructure and development costs for the portal would be needed, together with management and maintenance costs. It is important to remember that the rapid pace of IT evolution, coupled with increasingly intense competition for online learners means any primary players will need to commit very significant funding on a long-term basis.

Option 5: Pacesetter

Pacesetters may be traditional universities or commercial entities. *Pacesetters* contribute to the advancement of online learning, pushing the boundaries and defining the rules of the game. In addition to being a primary player, *Pacesetters* make major contributions such as:

- development of software for student-centred online teaching and learning

- development of new benchmark virtual university environments
- models for online interactive support of online students
- evaluation of virtual university outcomes
- business models for an online virtual university
- models and templates for effective online course development
- adaptation or development of effective administrative systems
- integration of on-campus and online flexible delivery
- models for the management of staffing and workload issues
- partnerships with other providers
- commercialisation of intellectual property

Funding implications: *Pacesetter* status results from a strategic commitment to deliberately pursue this position on the playing field. It requires significant prompt and ongoing realignment of resources, as well as resource enhancement through major grants, partnerships, and commercial arrangements.

Conclusion: Strategic Planning Recommendations

A university may target different levels of Web involvement for different markets or different curricular areas. A key criterion for targeting resources should be identification of the university's strong and strategic course offerings, as well as those of emerging strengths and strategic significance. However, the university as a whole must also choose appropriate targets to provide the underlying marketing, and technology and staffing arrangements required by the academic programs.

Online teaching and learning does not offer universities a 'sure bet' opportunity for increasing enrolments, reducing costs, or enhancing their reputations. The online learning market is highly competitive, yet the parameters of success in that market are not yet clearly defined. A prudent business-like approach to the possibilities, challenges, and risks e-learning presents would encompass market research including identification and analysis of potential partners and competition, analysis of expertise and resources within the university, strategic direction and priority-setting, an evaluation of the university's technical and staff readiness, plus careful cost-benefit and risk analysis.

Designing E-Learning Success:
Curriculum Design that Encourages Student Success

Stephanie Delaney
Instructional Design
Highline Community College
United States
sdelaney@highline.edu

Abstract: It can be challenging for some students to succeed in an e-learning environment. One way that instructors can insure online success is to design success elements into the curriculum of the course. Success elements are, quite simply, components of a course that facilitate student success. This brief paper explores the idea of success elements as a tool for reviewing whether new or existing e-learning courses facilitate student success. The paper goes on to explore several types of success elements that instructors can integrate into their curricula that will improve student success without significantly adding to the instructor's workload. Success elements will also help the instructor to have a better idea of how the class as a whole is absorbing the course material.

Introduction

Faculty in higher education complain regularly about how the work of their students disappoints them. Students are unable to write well, unable to cite properly, unable evaluate the quality of research sources . . .the list goes on. Rather than complain about poor student work, this paper proposes identifying the elements which are most troublesome and giving the students the tools they need to do what is required and to do it right. These tools are identified here as success elements. Many will view this as handholding that should not be necessary with today's college students. However, for those who are willing to accept that students are not as prepared as they wish and are willing to do something about it, they will be rewarded with higher quality work, less time spent grading and much less teaching related frustration.

Evaluating Curriculum

The first step in creating success elements is to identify the problem areas in a course. This is most easily done while grading student work or after calculating final grades. Determine the areas where students tend to falter or fail to live up to your expectations.

Case Study – Inadequate Papers

One instructor notes frustration with students who fail to ask questions about an assignment before turning them in. Rather than ask for clarification on an assignment, students would e-mail the assignment with a note saying that they hoped the work was ok since they had run into some hurdle that they could not get over.

To address this problem, the instructor began providing web links to the type of information that students claimed they could not find. She gave them as starting points and discouraged the students from using the provided resources in the papers. However, once the students saw what type of site they were looking for, they were able to find additional resources and consequently turn in better work.

Most instructors can quickly and easily list the top five or ten problem areas for students. Go through your own class and start a list of the problems that crop up. You may want to keep a running list while you are grading student work. Note any comment that you make more than twice – that is probably a place where a student success element would be useful.

Keep in mind that student inadequacy often goes beyond academic concerns. Students may be unable to manage time well enough to turn in a paper in time, may not have a computer at home, or may have domestic issues which interfere with the ability to study and complete assignments. While few faculty wish to get involved in the personal lives of students, simple success elements can assist the student in managing personal shortcomings more effectively. Interestingly, the elements designed to help the struggling student often assist the high achieving students as well.

Determining Success Elements and Incorporating them into the curriculum

After you have determined where students are having problems, you can begin to identify solutions. Sometimes a solution is as easy as giving the students more information. Other times, an assignment may need to be restructured to assist students in surmounting common hurdles. Here are a few practical suggestions that you might find useful in your own class. Keep on mind that finding the appropriate success elements is often an ongoing experiment. Soliciting student feedback throughout the class can result in some great ideas.

Pre Class Assignment

Online classes often require certain basic technical skills – the ability to download a document, to send an attachment, to do basic web searching, and so on. Students may say they know how to do these things, but they sometimes overestimate their abilities until it is too late. To address this problem, a pre-class assignment may be a good tool.

In one case, the pre class assignment is given to students about 2 weeks before the class begins. Students are asked to complete a series of simple tasks before the first day of class or on the first day of class. Tasks include finding a basic piece of information on the Internet, downloading needed software, buying the textbook and creating a schedule with the proposed hours of study. Students are asked to e-mail the assignment to the instructor as an attachment, testing that skill as well. This assignment gives students the opportunity to test their abilities in a non-stressful situation, outside of class. The two-week time period gives students the time to acquire some of the more basic skills before the class begins. If the student realizes that they do not posses needed skills, they still have time to select a different class.

Week One Monitoring

The first week of class can be challenging to e-learning students. They may be confused about how to start the class or how to proceed once class begins. Students may not realize the importance of reading and following *all* of the directions and as a result miss important information. Also, students new to e-learning are often challenged by technical problems in the early days of a class. Detailed monitoring of students can make the process much easier for the student and, in the long run, for the teacher as well. The monitoring generally consists of tracking each student on a daily basis and following up immediately when the student fails to meet a deadline.

A simple first step in week one monitoring is to ask each student to contact the instructor by email on the first day to insure the instructor that the student has been able to access the course materials and is doing ok. Students who fail to contact the instructor get a follow-up e-mail the following day and a telephone call the day after that. This helps identify those students who did not think to check their e-mail for information about their online class or those who got stuck and figured the problem would somehow resolve itself. The personal contact from the instructor makes students feel less isolated in the online environment.

Another week one monitoring activity is to have something simple due early on. Examples include biographies, student home pages, textbook exercises and the like. Those who fail to submit work in a timely manner are contacted by e-mail and telephone.

Another, more time consuming, monitoring project is to reply to all email within an hour of getting the message, when possible. The downside for the instructor is that they are practically glued to their computer for the first week. The upside is that students get a sense that the instructor is there, cares for them and is attentive to their needs. This impression lasts throughout the term, even after response times return to normal. This connection with the instructor also results in higher retention rates.

It is generally advisable to notify the students when the intense monitoring period is over (though they may not have been aware it was going on) and to set out contact expectations in that message.

Syllabus Quiz

Students frequently disregard information in the syllabus, even when that information is read to them in class. In the early days of an online class, students suffer from information overload and are likely quickly scan the syllabus or to skip it altogether. A short syllabus quiz is an ideal way to insure that students are attentive (at least at the beginning of the course) to the important elements of the syllabus.

Most courseware enables faculty to set up objective, automatically graded quizzes so that, once the quiz is created, it is little work for the instructor to administer. For those without a course management tool, a quick short answer or objective quiz can achieve a similar result. Encourage retention of the important elements of the syllabus by including syllabus questions in every quiz or exam as a bonus point or easy question.

Hyperlinked Rubric or Criteria list

Many faculty members have lists of criteria or rubrics that they use to evaluate student work. One way to improve student work is to give students access to that criteria and hyperlink each of the elements to an example and additional information.

For example, proper formal essay structure may be required in an assignment. List that in a criteria list or rubric and hyperlink it to an example of a properly formed essay. Identify the portions of the essay that make it particularly noteworthy and explain why. Ideally, this example would be a student answer, letting students know that the level of expected work really is possible. In addition to the example, the instructor could link to campus and online resources where the student who has trouble with essays can go for help. This might include links to the campus writing center and reference librarians as well as online writing labs and tutorials on essay writing.

The instructor can benefit in two ways. First, the general quality of work improves. Second, when students do turn in problem work, rather than writing lengthy explanations about what was wrong with the essay, the instructor can refer the students to the existing helpful resources. Some instructors even ask the student to write a comparison of their own work to the model and to rewrite the problem area(s) based on that critique.

Peer Grading

There are many ways to incorporate peer grading into a curriculum. From the perspective of student success, peers can review the first draft work of classmates using a set of criteria set by the instructor. This enables the peers to catch common problems overlooked in the haste of assignment preparation – poor grammar and spelling, improper formatting, and other basic problems. Depending on the class and the students, more sophisticated problems can be corrected. Either way, the result is improved work from the student and less grading time by the professor.

Incorporating peer grading into the curriculum is generally as simple as adding an additional due date a few days before the final assignment is due. Sometimes additional days will be required so that the reviewer has time to read it and to make meaningful comments and that the reviewed student has time to rewrite the assignment.

Summary

The ideas presented here are, for the most part, not new ones. What may be new is the holistic and systematic approach to improving student performance by taking greater responsibility student success. The concept of incorporating success elements into the curriculum is a series of actions that a faculty member can take to improve the quality of student work while reducing time spent grading and banging ones head against the wall in frustration. The initial investments of time are often modest and the products can frequently be used in more than one class, term after term. The next time you identify a frustrating yet typical student behavior, take action and address it.

A DISTRIBUTED LEARNING MODEL FOR PROBLEM SOLVING AND PROGRAM DEVELOPMENT

Fadi P. Deek and Idania Espinosa

ABSTRACT

Technological advances are paving the way for improvements in many sectors of society. Traditional education has primarily been teacher driven, lectured-based in one location. Distributed learning is an emerging paradigm that can contribute significantly to the learning process. This paper explores the difficulties novice programmers' face when learning to program and proposes how distributed learning can be used in learning problem solving and program development.

INTRODUCTION

Novice programmers have difficulties in breaking down a given problem, designing a working solution, and debugging a program. Many programming environments, software applications, and learning tools have been developed to address these difficulties [2][3][4][5]. Several factors play a role in developing problem solving skills and program development in students. Achieving these skills is based on the internal cognition of the individual, the instructor abilities, environmental factors and the programming language. Why do novices have such difficult time learning to program? This question is answered from different angles: student, teacher, and programming language. Novice programmers normally find programming frustrating and difficult. They may not have the sufficient preparation to grasp concepts that are abstract and complex. Novices are not familiar with designing and testing logical structures for solving problems by computer. They lack an adequate mental model about the internals of a computer and how it operates. Some programming teaching methods are also a factor that hinders students' ability to learn, such as the over-emphasis in introductory computing courses on language construct and programming syntax [2][6] and not on problem solving skills.

LEARNING STYLES

Educational research shows that students have different styles of learning. These learning styles can be identified based on the type of information students prefer to receive: sensory or intuitive, visual or verbal, inductive or deductive, actively or reflectively, and sequentially or globally [1]. Instructors should mold their teaching styles to that of students' learning styles in order to effectively maximize learning in classroom.

Sensing learners tend to retain information like facts and observations. They process information more effectively through sights, sounds, and physical sensations. They are detailed oriented and prefer solving problems using well-defined steps. They are practical and complain when information is not related to the real world. Intuitive individuals, on the other hands, are more imaginative and thus prefer abstract concepts and information that is open to interpretation. They rely on memory, ideas, and their own insights. Sensing learners tend to get lower grades than intuitive learners do on lectured courses.

Visual learners retain information through images more so than verbally. They perceive information more effectively via diagrams. If a lecture does not incorporate some visual representation of a concept, visual learners have the tendency to forget the material. Research shows that most students in science classes are visual learners [1]. Lectures are mostly verbal with abstract concepts, formulas, and few diagrams. Verbal learners learn based on written and spoken words.

Inductive learners learn based on first specific scenarios and then more general principles. Students tend to use given facts and observations to infer principles. Deductive learners, on the other hand, prefer general principles first and then deduce consequences. Research shows that inductive learning promotes a deeper understanding and retention of information. Classrooms tend to use deductive approach [9].

Active learners prefer group discussions and exchanging ideas with others. Reflective learners tend to think things through and then experiment. They prefer individual work or in pairs. In a lectured course, both groups are actually neglected and enforce a passive approach to learning. Studies show that students in an active environment excel in comprehension, memory retention, and problem solving. [7]

Sequential learners gain an understanding of information in small, connected pieces. They solve problems efficiently, but may lack an understanding of the larger problem domain. Global learners' approach is all-or-nothing. Initially, they may appear to be slow students, but once they grasp the larger picture, they can make connections that sequential learners do not identify.

DISTRIBUTED LEARNING: AN ALTERNATIVE TO LEARNING PROBLEM SOLVING AN PROGRAMMING

A new model of learning has emerged which collectively brings together these models. This is distributed learning. This section describes this model of learning and also describes the solutions to existing problems in programming. According to Syllabus Magazine in 1995, distributed learning is not just a new term to replace distance learning. Rather, it comes from the concept of distributed resources. Distributed learning is an instructional model that allows instructors, students, and content to be located in different, non-centralized locations so that instruction and learning occur independent of time and place.

Programming using distributed learning model serves as microcosm of the future of learning whereby learning can take place both inside and outside of classrooms. The boundaries have been removed and interactions with people from different locations and different times are possible. The use of distributed learning in computer classrooms provides a new direction for teaching. It resolves the many difficulties that have been observed by novice programmers in learning software development. Below is a summary of difficulties encountered by students and the provisions needed along with a distributed learning environment to resolve these issues.

1. Lack a mental model to visualize abstract relationships
2. Instructors in traditional learning hold an important role in transferring knowledge. If instructor is lacking social skills necessary for interacting with students, technical ability, or effective speaking, an impediment for learning results
3. Students fall behind in classrooms and miss fundamental concepts.
4. Lack of motivation

5. Limited knowledge in a scientific area which may result in difficulty in interacting and following complex discussions
6. Students passivity in class
7. Small programming assignments which tend to lead to individualistic work habits
8. Deficiencies with traditional teaching methods, esp. lectured-based teaching
9. Emphasis on competition for grades rather than learning
10. Programming language paradigms do not associate with natural tendencies of problem solving.

The difficulty of mentally representing abstract concepts is overcome by the use of visual modeling tools. Sensory immersion devices assist in visualizing abstract concepts. These devices have been successful in areas of science and medicine. Once this is extended to the computer world, novices will be better able to model abstractions.

Distributed learning provides alternate means of learning than traditional teaching methods. By allowing students to engage in collaborative learning exercises and to use visual modeling tools, they can spread their depth of learning. The goal is to provide a more enriched curriculum that can guide students to achieve maximum learning potential. Interacting with students could enhance cognitive skills and complement individual cognition.

Distributed learning offers a solution to the third difficulty described whereby students fall behind in class. Virtual classrooms can provide additive means of learning, such as discussion forums, so in the event that a student falls behind, other sources of information are readily available to bring students up to speed on misunderstood materials. For students who prefer learning at their own pace, distance learning course can facilitate this.

CONCLUSIONS

Distributed learning has great potential to be the wave of the future in academic development in support of learning without boundaries to time and distance. It offers a wider spectrum of instructors, advisors, and collaborators than in any single educational institution. It provides a means of attaining skills from remote sources and collaborating with dispersed team members. Technology provides the essential tools for establishing interactions, but these tools, if misused, could lead to adverse effects. A balance is necessary between virtual and direct communication within group members in order to develop and sustain a sense of community. Interactions based on phone conversations alone lack the vibrancy of face-to-face. Also, while technology-mediated communication (i.e. teleconferencing, digital and video) will open the doors of virtual interactions over various information mediums, it will not completely replace personal contact. In order to optimize the use of the distributed learning model, provisions must be made and new inventions devised which provide the best of both worlds for learning. The future of distributed learning is via collaborative virtual workspaces and sensory immersion devices [8]. Further studies are necessary to measure the performance of dispersed team members using CVW. More research is also needed in the area of sensory immersion to study the impacts of these devices in the (virtual) classroom. High performance computing will gradually enable virtual communities to make possible face-to-face interactions and sensory immersion to be an integrated part of everyday life.

Abstract: This paper shows the importance of taking account of the structure in order to describe and retrieve educational resources. Each educational resource is associated to metadata and structure. We propose combining the structural and the textual analysis of the resources to improve the performance of the system. The user is able to manipulate information at several levels of abstraction, for example a set of resources, images, chapters dealing with one particular area.

Building Educational Resources

Nowadays, more and more educational resources are published and accessed through the World Wide Web (WWW). But educational resources on the WWW lack explicit semantics and structure. This can be improved by the use of metadata to describe the semantic content and by the use of typed links to represent the structure of the resources. Standardized metadata such as Dublin Core Education [1], LOM [2] bring better understanding of the educational resources content and aim, but there is a little description of the structure of these resources.

In order to underline the importance of taking into account of the structure, we classify various types of links that we can find to relate educational resources. Links of structure: they represent the logical structure of a resource, either the inclusion, the sequencing of parts of a resource (for example, the list of prerequisites).

Links of semantic association: these links reflect a semantic association between two pages, or two concepts and are very diverse because they concern the cognitive aspects of the author. Indeed according to the context, the term "winter" can suggest cold, season, country etc. Links of navigation: purely functional, they are used to physically cut out a text in a set of pages limited in volume (number of bytes). They are used for navigation between the pages, for example back link, return to the home page. Links of references: they are used to reference to pages in connection with the subject, for example the bibliographical references, or the references to similar sites and personal pages.

All of these links are often chosen by the author during the building of pages, but the types of links are not explicit with the Hypertextual Markup Language (HTML). To mitigate these problems, we consider that a educational resource is either an atomic unit of information such as an image, a passage, a title…, or a composition of other resources. A resource can be defined as a semantic unit of information, autonomous in the sense that it can be given as a response to a user request. From there, we can consider different levels of resources. A global resource can be structured in a hierarchy of several resources, it is composed of structured elements representing either section, paragraph, image, sound, graph called resources too. Each level in the hierarchy corresponds to a different level of granularity. We choose a tree structure of nodes for our example to be understandable, but in fact, we can have a Directed Acyclic Graph (DAG) structure. For example we can have a first organization level, composed of several domains, sub-domains and so on. Each hierarchical level represents a level of granularity, the lowest level of granularity is that of the components of the atomic resources (not decomposable). This concept of granularity is significant because it intervenes in all the stages of our new information retrieval system. Indeed, during the description of the resources, our formalism makes it possible to describe resources, to express the structural or semantic relations between the resources, to adapt this description to structured pages with the HTML format (META tags) or XML (the tags are defined by the author of the pages according to a particular DTD). Thus, it is possible to explicit the various types of relations between resources, between components of various natures (multi-media like its, image, video) or of various types like paragraphs, references, summaries...

The semantics and the structure of resources as we specified previously may be done by the author of the pages, manually, thanks to metadata. A classical hierarchical clustering algorithm can determine the hierarchy of resources and provide the summary of each cluster. The first solution enables a precise control and the labeling of each represent of clusters by the author, but it requires human help. The second solution is completely automatic but the drawback is that the labels

BEST COPY AVAILABLE

are a list of keywords extracted from the resources and maybe some concepts are omitted. For a quality reason and to enable the author to control the indexing phase, we build the structured resources with the help of the author of resources.

In the building phase of the educational resources, we propose to describe the resources using the IEEE LOM[2] semantics and to apply the RDF serialization[3] with the XML syntax[4].

In the following sections, we take the same example of an E-learning Web course delivered at Supelec's school. In this example, there is one "computer science course" resource which is composed of other resources. The educational resource material has been created by Yolaine Bourda. The domain of the resource is the database management systems (DBMS), including the SQL language. The courses are currently used by students both in Paris and in different geographical places of the Supelec's school: Metz and Rennes. Firstable, the audience is the Supelec's students but it can also be extended to any elearner who can access the http://wwwlsi.supelec.fr/www/yb/poly_bd/ site. This is an example of the LOM metadata describing three resources:

The e-learning resources and their organization are partially illustrated in figure 1. Through this example, the same author is responsible for the publication of the three documents (described beyond and illustrated in figure 1 by *d, d1 and d2)*, and the date of the creation is the same for the whole documents too; nevertheless, this piece of information has been omitted when the resources composing the root document have been described. This omitted information may be deduced thanks to the dynamic propagation of the metadata along the structural links. The first resource *d* represents the Web site as a collection of E-learning resources. Each resource is described thanks to the LOM metadata. *d* is composed of the two resources *d1* and *d2*. The classification of links categorizes the "isPartOf" and "requires" attributes as structural ones. Each attribute can be static or dynamic. Static means that the attributes are local to the resource and that they can't be propagated along the hierarchy of the metadata. For example, the "kind" and "identifier" attributes are static. "Dynamic ascending" and "dynamic descending" respectively mean that the attributes can be propagated along the hierarchy towards the root or towards the leaves. For example, in figure 1, "author" is a dynamic descending attribute, therefore every resources composing *d* inherit from the value of author. "Keyword" is both an ascending and a escending attribute, so *d21* is indexed by keyword = syntaxe + query whereas *d211* and *d212* are indexed by keyword = course + computer science + SQL + query.

Figure 1: A partial organization of a hierarchy of educational resources

Accessing Educational Resources

Let's assume that DB is the corpus of the resources. In order to support the new functionalities we introduced in our paper, we defined a new query language that supports:

- dynamic granularity of the response, i.e. the granularity of the resource (a chapter, a section, an image) is not expressed in the query but determined by the information retrieval system with the evaluation function at the request time,
- querying on metadata attributes of each resource,
- combination of multi-typed requests allowing the system to manage requests against resources of various types.

The relevant documents in response to a query can be computed with the following evaluation function: where *R* is the relevance rate of the document and *pi* is the weight of each attribute of metadata. *di* is a distance associated to the level of propagation of the attribute.

$$R = \sum_{i=1}^{n} p_i \times \frac{1}{1+|d_i|}$$

$$p_i = \frac{1}{n}$$

We opt for an OQL-like syntax defined by the ODMG[5].

We give two examples showing the power of expressiveness of the query using both metadata and

BEST COPY AVAILABLE

structure.

Query 1: find documents dealing with both "query" and "update" whose author is "Yolaine Bourda"

`Select d from DB where d.lifeCycle.contribute.entity="Yolaine Bourda" and d.general.keyword="query"+ "update"`

Thanks to the ascending propagation of the "keyword" attribute (figure 2), the evaluation function returns *d2* as the most relevant answer with the score: 1/2.

Query 1: find SQL courses in computer science published after 1995

`Select d from DB where d.lifeCycle.contribute.date > "1995" and d.general.keyword="SQL"+ "course" + "computer science"`

Thanks to the descending propagation of the "keyword" attribute (figure 3), the evaluation function returns *d2* as the most relevant answer with the score: 1. *d21* and *d22* where candidates too, but their scores : 1/3 are less than *d*, (note that the level of granularity of *d* is bigger than the *d21* or *d22* one).

Conclusion

Classical information retrieval systems provide static responses (fixed by the pre-defined granularity of resources), without taking into account neither the structure of a resource nor its semantics. Here we explain how to explicit the structure of educational resources, and we suggest a new information retrieval system that can index and search educational resources organized into multi-typed resources. This will enable end-users to request in a powerful semantic query language and to provide more suitable responses at several levels of granularity.

Connecting the Dots: Uniting Education Around the World

Laura Diggs, Ph.D. & John Wedman, Ph.D.
University of Missouri-Columbia

This paper describes a current and ongoing effort to increase global awareness by providing a unique use of Internet2 and video for English instruction with international teachers and students, exchanging cultural information, addressing needs of learners from diverse cultures, and understanding the importance of providing enabling technology experiences that learners cannot have otherwise. The University of Missouri-Columbia College of Education (MU CoE) has implemented a globalization initiative and there are currently 4 schools in Taipei, Taiwan that are connected with K-12 schools in Missouri as well as MU faculty and pre-service teachers. This year, the MU CoE sent three faculty and staff members to Taipei to develop and implement a literature-based English curriculum for students to share with their American counterparts. The goals of this globalization initiative are a critical 3-part model that is a unique experience that currently does not exist. This experience evolves around information and learning, enabling technology, and global connections. This 3-part model is based on: 1) connecting a K-12 school in Taipei, 2) with a K-12 school in Missouri, and 3) MU CoE Literacy faculty. The connection is provided through utilizing Internet2 and video conferencing equipment.

The process of this globalization initiative focuses on individual school needs, but all involve utilizing technology to allow students to have email as well as face-to-face conversations to practice online communication, establish friendships with students of other cultures, exchange cultural information, and develop and understanding and tolerance for other cultures. Students from both cultures benefit from the opportunity to improve their English language (written and verbal) skills as well as identifying the benefits and limitations of online communications.

Current projects where partners include schools in Taipei working with Missouri schools include two elementary schools, one K-9 school, and one senior high school. Projects include development of web sites for descriptions and pictures of participating teacher and students, the school and surrounding community, special events and holidays, as well as information on foods and day-to-day life for students their age. Schools have participated in paired reading of English children's literature books and had face-to-face video conversations around the books. Several schools are participating in science projects together where they collect samples of vegetation, water, and wild life to compare and contrast on the web site with their partner school. With the time difference between Taipei and Missouri being a complicating factor, partners are sharing information through threaded discussions and emails as well.

The impact of this globalization initiative has proven to be beneficial to the Taiwanese students having authentic conversations with native speaking English speaking students their own age and improving their English writing and oral skills. The Missouri students have discovered a new cultural appreciation as well as developing friendships. The MU CoE faculty and pre-service teachers have acted as cyber-tutors to help in the writing process as well as professional development for the Taiwanese teachers.

This summer, three of the Taiwan schools are planning trips to Missouri to visit their partners and learn more about living in the United States. One school will have the opportunity to participate in the ThinkQuest Internet2 conference in Seattle, Washington after spending time in St. Louis, Missouri, taking field trips to Boeing corporation, St. Louis Science Center, and other points of interest. Students will collect digital photographs, movies, and other media objects to share as part of the conference and globalization initiative.

E-Learning : The Design of Cognitive Crutches in the 21st Century

Koen DePryck, Ph.D.
Center for Adult Education, Antwerp (Belgium)
Institute of Knowledge Management, Brussels (Belgium)

Abstract

This paper deals with the implications of evolutionary epistemology for the design of Learning and Knowledge Tools. Evolutionary epistemology brings to the table a set of concepts that allow us to construct new cognitive tools that, embedded in or connected to our evolutionary past, may contribute to our cognitive future.
Human cognition is neither static nor deterministic but has evolved, under evolutionary pressure, into a set of tools capable of interacting with those aspects of reality bound to enhance our potential for survival as individual beings or as a group.
Any meaningful design of IT-based Knowledge Tools will need to take that double evolutionary context into consideration. It must address

1. **the issue of providing input to a wide range of cognitive modules, many of which serve multiple cognitive function.**
2. **the issue of compatibility with a wide range of cognitive styles.**

We try to point at the relevant characteristics of our mental system and explore the systemic conditions the evolutionary context imposes on knowledge tools and knowledge management systems.

Paper

The history of human tool-making is also a history of crutch-design. A hammer is a fist. Power (most often electric power) has added a new dimension to tools but did not really change their nature—it just made them even more powerful. We have not only developed tools to decrease our physical limitation, we also developed tool to decrease our cognitive restrictions: magnifying glasses and telescopes, clocks, books, …[1]

Every tool is somehow connected to our cognitive wiring if not but for the simple reason that we use them. If that connection goes wrong because it is too complex or because it is poorly designed, the tool quickly looses its attraction and usefulness. The study of cognitive tools is therefore also a study in ergonomics and a study of interfaces.[2]

The study of our tools is a study of ourselves. In a sense, tools are a magnifying glass trough which we can look at our own design. Looking at the cognitive tools that we use can help us to peek inside our minds and to take a look behind the curtains of evolutionary pressure. But an understanding of how our mind functions should allow us to come up with new and exciting cognitive tools without having to rely too much on trial and error.

---

[1] Slide: list of physical and cognitive tools
[2] Slides: examples of how tools connect to our neural circuitry

When we look at educational software, for example, we find an incredible amount of utterly useless products. They simply don't resonate with our cognitive processes. They are like a beautifully sculptured hammer made out of glass: nice to look at, perhaps, but utterly impractical.

A VCR is a wonderful tool. Let us take a look at the buttons. Record (memory storage), play (retrieval), ff, fb, pauze, index (use of markers to facilitate retrieval), … It is not clear if each successful and often used function of the machine corresponds to a primitive 'human' cognitive function, although it is safe to assume that unsuccessful gadgets probably fail to connect to such a human function, except perhaps for a small and marginal group of people.[3]

Human cognition is neither static nor deterministic but has evolved, under evolutionary pressure, into a set of tools capable of interacting with those aspects of reality bound to enhance our potential for survival as individual beings or as a group (and thus indirectly as individuals). New technologies and e-learning will only be successful if they connect to our evolutionary history. At the same time, successful new tools are likely to profoundly change our thinking, our behaviour, our values, …

At the level of the species (or, if one prefers, at the level of individual selection) evolution has constructed, over millions of years, a set of cognitive modules and clusters of such modules. Individual modules define operations over inputs. The input can be either external, as in the case of sensory inputs, or internal, generated by the module itself or generated by some other mental subsystem. Furthermore, it is reasonable to assume that severalmodules originated as either backup or add-on to older modules, resulting in a by all means complex system.

Cognitive modules and clusters of such modules interact with proper as well as actual input domains. In the case of a module (perhaps constituted by more fundamental modules) for syntactic pattern recognition, actual sentence patterns make up the proper input domain, whereas a rather large set of auditory constructs (from babies' 'talking' to songs of birds and sometimes even mechanical noise produced by machinery) would belong to the actual domain without belonging to the proper domain.

As human beings, we generate huge amounts of actual but improper inputs. The use of IT in general and in education more specifically allows us to explore the boundaries of our mental modules and their interaction. Furthermore, it is not unreasonable to assume that the increasingly large amounts of improper input have an effect on the microcircuits of our cognition. Since a reduction of visual experience causes a reduction of the number and size of synapses in the visual areas of the cortex, a culturally increased amount of specific visual experience (such as we would find in specific types of interaction with computers) could lead to an increase in the amount and size of synapses required to handle that input to cognitive modules. The cortex of wild animals may be up to one-third thicker in wild animals than in domesticated ones, something Darwin already noted.

---

[3] Slide: picture of VCR as a cognitive tool, relating buttons to cognitive functions.

For obvious reasons, the production of improper input to our mental system is greatly restricted by the characteristics of that system and its larger environment, although some degree of randomness, noise, and perhaps coincidence may not be avoided.

In this paper, we try to point at the relevant characteristics of our mental system and explore the systemic conditions or the constraints that the evolutionary context imposes on knowledge tools and knowledge management systems.

Our cognitive system can be described by number of aspects:[4]

- Input
  - Visual, auditory, tactile, kinaesthetic, olfactory
  - Verbal, non-verbal
  - Proper, improper
  - Focus
- Content
  - Paradigms
  - Need-based, interest-based, …
- Processes and operations
  - Differentiation, categorization, seriation, logical deduction or induction, analogy, counting, mapping, …
- Learning
  - Implicit, explicit
  - Speed, …
- Level of abstraction
  - Distance from information present in sensory input
- Level of complexity
  - Number of units of information, degree of novelty, ..
- Storage
  - Memory
  - Retrieval
- Output
  - Cfr. Input
  - Communication

The specifics of each of these aspects have been shaped under evolutionary pressure in a relatively stable context. IT and E-Learning dramatically change that context. In order to maximize the usefulness of cognitive tools, we must identify their strengths as well as their weaknesses and compare those with our 'innate' tools. It is only on the basis of such an inventory (perhaps also including characteristics of successful 'older tools, such as books) that we will be able to integrate existing E-learning tools successfully and to design new tools that are even more powerful than the ones we have available today.

Mathematics is bound to play an essential role in the development of meaningful new tools. Pattern recognition, typically something humans are fairly good at, can be enhanced by teaching computers how to deal with pattern. Understanding how we handle patterns will allow us build tools that are even better at doing that than we ourselves are.

---

[4] Slides: overview of the aspects of a human cognitive system

Nevertheless, the relationship between innate and the set of new tools is typically ambiguous. Computers make it easier to count. Databases enhance our memory. On the one hand, new tools obviously outshine a number of our innate functions, perhaps contributing to their decline. On the other hand, they make it possible to train our innate functions or to compensate for deficiencies. Children playing games on their computers develop superior eye-hand coordination. Foreign languages are more easily learned using speech technology and sound analysis, vocabulary is more easily memorized with the help of appropriate software. Even common word processors can help people with language problems (dyslexics, ...) by incorporating tools such as speech recognition, spelling correction and functions to find homonyms.

E-Learning exists at the somewhat paradoxical crossroad of making us less dependent on the restrictions of some of our innate functions and the enhancement of others. E-Learning must therefore be approached as part of a larger epistemic system that includes our innate as well as the totality of the cognitive tools that we have developed throughout our history.

That is especially important if we take the distribution of cognitive functions in a population into consideration. At the level human social interacting, (or, if one prefers, at the level of group selection) evolution has come up with a range of cognitive styles, ranging from the predominantly verbal to the predominantly non-verbal, from the predominantly inductive to the predominantly deductive, from the predominantly synthetic to the predominantly analytic, and so on.

Any meaningful design of IT-based Knowledge Tools will need to take that double evolutionary context into consideration.

1. At the level of the individual, it must address the issue of providing input to a wide range of cognitive modules, many of which serve multiple cognitive functions.
2. It must also address the issue of compatibility with a wide range of cognitive styles, avoiding a simplistic reduction of human cognition to a single evolutionary thread or, worse, a single static set of cognitive functions.

In conclusion, I argue that E-Learning tools must be sufficiently 'traditional' in order to change our traditional ways. In the design of educational software, all too often too much energy is spent trying to make something 'unique', something 'different'. While that may appeal at first, in the long run it tends to decrease the chances to make a truly lasting contribution to a genuine learning society.

Providing Higher Education Degrees Through Telecommunications and Collaborations

Rita L. Dobbs, Ph.D., Department of Technology, The University of Texas at Tyler, USA, rdobbs@mail.uttyl.edu
W. Clayton Allen, Ed.D., Department of Technology, The University of Texas at Tyler, USA, callen@mail.uttyl.edu

Abstract: **This paper will provide critical information to interested higher education personnel for designing/implementing undergraduate/graduate degree programs utilizing telecommunications, collaborations, and technical support services. Collaborations among the Mexia State School, a MHMR facility, The University of Texas at Tyler (UTT), and the UT TeleCampus, a virtual university designed as a central support system for the 15 component campuses and research facilities that comprise the U T System, allow students to obtain degrees that would have previously remained unattainable. The Department of Technology at UTT provides custom designed degree plans through a combination of interactive television courses, web-based courses, and academic credit for work experience to grant degrees in appropriate fields. Technological support, tutorial programs, and digital libraries are among the essential support services provided to participating students.**

As The University of Texas at Tyler (UTT) steps into the new millennium, a new era will be much more complex and demanding than the last one. It will be characterized by rapid changes in demographics, growth of an information-age economy, and revolutionary technological advances. The 21st Century will also place new pressures and demands on universities to be more accountable and more affordable, to serve an increasingly diverse society, and to deliver education using alternative models. The University must be positioned to meet these realities in order to prepare students to meet the challenges of a fast-paced and shrinking world. The University of Texas at Tyler welcomes the challenge, and in doing so will become the distinctive choice for those seeking academic excellence, opportunity for personal and professional growth, and a dynamic environment for learning in the new millennium.

UTT was established by the Texas Legislature in 1971 as Tyler State College and was renamed Texas Eastern University four years later; it became a component of The University of Texas System in 1979. UTT became a four-year university by action of the legislature in 1997; it had been created as an upper-level university.

Challenges for Students

University students will need to *take more responsibility for their learning*, for exploring and understanding complex concepts, and for accurate analysis and creative synthesis. They must become fully engaged, active partners in the educational process, learning to navigate through the rich information environment that exists outside of the classroom and challenging themselves to become intellectually vigorous in order to acquire, evaluate and use the information available to them. In short, students must not only learn, they must also acquire the skills to learn effectively on their own.

Challenges for The University of Texas at Tyler

The University of Texas at Tyler is transforming itself into a four-year, comprehensive, regional university with a full range of undergraduate and graduate degree programs. Only a comprehensive university that emphasizes the integration of

BEST COPY AVAILABLE

liberal arts and professional education can provide the depth and breadth of knowledge, skills, and attitudes that students will need for success in the new millennium.
The University will respond by creating the "U. T. Tyler Tradition"-a solid foundation for successful learning that is based in the humanities, arts, and sciences and that fosters rigorous intellectual growth and academic development in all disciplines. The "U. T. Tyler Tradition" will provide the "cornerstone" for preparing students to accept and even anticipate the multiple transitions they will make during their lives. This distinctive curriculum will provide the necessary base of knowledge and engage students in self-discovery where they develop the art of reflection and embrace intellectual challenges.

The Department

The Department of Technology is a student-centered department committed to conducting multi-option programs targeted at preparing technical professionals, instructors, and educators who exceed standards. In accordance with this statement, the Department of Technology continually strives to improve the array of managerial and technical knowledge and skills of individuals by offering programs and courses based on industry's need for applications oriented, technically competent, flexible and internationally competitive employees. In order to ensure that the program offerings are technically up-to-date, the Department employs laboratory instruction based on tabletop technology and computer-based simulation.

The Department of Technology has adopted the NAIT definition of Industrial Technology. It is viewed as a field of study designed to prepare technical and/or technical management oriented professionals for employment in business and industry. The programs in the Department include:

1. The application of theories, concepts, and principles found in the humanities and the social and behavioral sciences, including a thorough grounding in communication skills.

2. The understanding of the theories and the ability to apply the principles and concepts of mathematics and science and the application of computer fundamentals.

3. The application of concepts derived from, and current skills developed in, a variety of technical and related disciplines which may include, but is not limited to, materials and production processes, industrial management and human relations, marketing, communications, electronics, and graphics.

These concepts have served as the basis of an ongoing program and curriculum improvement process throughout the history of the Department. As a result of this commitment, the Department of Technology entered into an agreement with the personnel of the Mexia State School to offer undergraduate and graduate programs via interactive television classes (ITV) and through web-based courses offered through the UT TeleCampus component.

Mexia State School

Mexia is located approximately 100 miles southwest of Tyler. Personnel at the Mexia State School previously had to travel to Waco to take courses from Baylor University, a private institution where tuition rates were proving to be prohibitive for the personnel wishing to continue their education.

Today the school employs almost 1,500 individuals. The school operated exclusively from wooden barracks until June 1951, when the first permanent brick buildings were completed with beds for 312 boys. In September 1953, a second group of buildings was completed with 425 beds. Money for this early construction came from a one cent a pack cigarette tax levied by the Texas Legislature. Construction of new buildings continued through the 1950's with the completion of additional dormitories. A 50-bed infirmary was opened in 1958. In 1963 the peak period of construction ended with the dedication of 14 new buildings on the state school campus.

During the past years, the school's population has changed as other services became available in the community. From its origin has a home for young men and women with various levels of mental retardation, the school has become a place where individuals with profound and severe retardation in addition to behavior and medical problems live. The average age of the school's residents is now 45 years old. Mexia State School is a regional operation of the Texas Department of Mental Health and Mental Retardation. (Mexia State School)

Providing Degrees for Mexia Students

In order to meet the needs of the Mexia students, a special undergraduate degree was made available to the students, the Bachelor of Applied Arts and Sciences (BAAS). This degree program has been identified with the "inverted curriculum." It gives primary consideration to areas of emphasis meeting the educational and career goals of community and junior colleges. Only students who have specialized at the junior college or community college level in technical or vocational studies and desire to continue in their pursuit of a degree may follow a program leading to the Bachelor of Applied Arts and Sciences degree.

The courses, which lead to the degree, may differ from student to student, making it possible to customize the degree program to fit a student's needs. The purpose of this program is to provide opportunities for those individuals planning to enter the technical or vocational occupations, or for those who have already entered the technical or vocational occupations but have decided that additional educational preparation will strengthen their previous training and improve career advancement opportunities. A student may also prepare a professional dossier of past work experience for consideration of academic credit up to 18 semester hours. This allows the personnel at the Mexia State School to complete their undergraduate degree. The courses for the BAAS are offered to the Mexia State School through ITV courses that originate at UTT and are transmitted to Mexia through a T1 line via compressed video. Mexia students are able to conduct counseling sessions and student conferences through the ITV system. Professors from the Department of Technology travel to Mexia at least one time during the semester to make a personnel contact with students and to help assimilate them into campus life.

UTT library provides digital resources for the remote students. Complete instructions for accessing the electronic databases as well as instructions for requesting interlibrary materials are in place on the library homepage found at http://library.uttyler.edu/distance.htm

Students in Mexia who are pursuing the Masters of Science in Technology/Human Resource Development (HRD) option have two options available to them. They may take courses through the ITV system or they may take courses through the UT TeleCampus. The HRD degree option can be customized to meet the particular student's area of interest and can accommodate the interests and special skills of each student. Professors in the department meet with each degree-seeking student individually to construct a degree plan that is perfect for that student's career goals. The success of the program has been tremendous with the growth of the program exceeding double digit increases each year.

Human Resource Development is a professional field of practice that focuses on education and training of adults in diverse settings. It is organized learning activities arranged within an organization in order to prepare young people to manage the dual roles of family member and wage earner, to enable them to gain entry-level employment in a high-skill, high-wage job and/or to continue their education.

The online Master of Science degree/HRD option utilizes the resources of UTT, The University of Texas at Galveston (UTG), The University of Texas at Permian Basin (UTPB), The University of Texas at Arlington (UTA), and the UT TeleCampus. The Department of Technology assumed responsibility for developing nine (9) courses in the

MS degree option and utilizes 6 courses from the component institutions. This truly makes the MS degree in Technology/HRD option a unique opportunity, not only for the personnel of the Mexia State School, but also for the citizens of Texas and beyond.

The UT TeleCampus (UTTC) is the support center for online learning within the University of Texas System's fifteen component campuses. Online courses and degree programs can be completed entirely at a distance and meet the same high-quality academic standards as their onsite equivalents. The UT TeleCampus provides everything a student needs to participate, including admission applications, registration and financial aid information, classrooms and academic resources. The goal of the TeleCampus in placing programs online was the creation of collaborative degrees, utilizing the best resources in faculty expertise from all campuses. This was the model followed in developing the Master of Science Degree in Technology/HRD option.

"An excellent example of the expanding e-learning programs offered by state university systems, the UT TeleCampus was launched in 1998 by the University of Texas System. Students may earn an MBA, Masters in Computer Science, and various other online degrees from a school within the UT system. Students who wish to earn a degree must first apply and be admitted to one of the universities in the UT system. That campus will then serve as the student's "home" campus, and ultimately award the degree," Dr. Darcy Hardy, Asst. Vice Chancellor for Academic Affairs and UT TeleCampus Director.

Conclusions

In order to participate in a UT TeleCampus online course, certain computer requirements and browser configurations and plug-ins are needed to enable a successful experience. Online students must also have a confident level of computer literacy.

An important part of an online course will involve Web conferencing and other interactivity such as synchronous chat. These tools provide a means for communicating with the instructor and classmates much like a student would in a face-to-face environment.

By using the "Getting Started" CD-ROM, published by the UT TeleCampus, a student can start the semester with the advantage of being able to receive all multimedia aspects of any given course. Necessary software requirements are consolidated on one easy-to-use CD provided by the UT TeleCampus and mailed to each student enrolled in the online program. (UT TeleCampus)

Extensive support services are provided by TeleCampus staff in the way of instructional design and course development, as well as faculty training in bringing courses from the lecture-based classroom to the Web-based classroom. Technological support, policy, marketing research and external communications are among the other essential support services provided to the campus from the UT TeleCampus (UT TeleCampus).

The Department of Technology at The University of Texas at Tyler is striving to provide quality educational programs to students who wish to pursue their educational career goals. By collaborating with specific institutions, UT components, and the UT TeleCampus, the Department of Technology is bringing higher education degrees to the citizens of Texas and the world.

Technology, Education and Knowledge: Digital Divide or Knowledge Leverage ?
-Some Thought Following a Pilot Project of the European Commission-

Patrick-Yves Badillo and Dominique Bourgeois
Research Center on Media, Information and Knowledge
University of Aix-Marseille II (Université de la Méditerranée)
France
badillo@ejcm.univ-mrs.fr

Abstract: Knowledge is a key factor in the new information society and technology induces a considerable demand to the education systems. The virtues of a "socratic school", resting on four pillars: to learn how to know, to learn how to make, to learn how to live together, to learn how to be, must be accessible thanks to the use of the information and communication technologies. Form-Ami is a pilot project of the European Commission with a view to promoting new university training courses in the specialized skills required by the information industries. Form-Ami can be considered as a reference for the diffusion of a new pedagogical paradigm. We will show how the new pedagogical and knowledge mediation is a key for the future. But, to break the digital divide will be more and more costly at the beginning. Only later the fruits of these efforts will be available...

> *"The illiterate of the future will not be the person who cannot read.*
> *It will be the person who does not know how to learn."*
> *A. TOFFLER quoted by I. PRIGOGINE, letter, 1999*

Need for Radical Teaching Innovations... to Surmount the Knowledge Gap

The harmonious development of the information society depends *on the coherence of the "triptyque": technology - education - social diffusion. The technological push* made possible to develop networks which store, treat and convey an increasingly significant quantity of information. A new training paradigm appears with the rise of the Information and Communication Technologies (ICT); the usual teaching actors have to make a difficult and long adjustment: training and knowledge are accessible with new methods thanks to new technologies. Remote teaching becomes a distributed teaching in which the learner plays an increasingly active role in interaction with the teacher. *Beyond the technological development much more significant breaks become visible concerning "Knowledge" and its diffusion.* In the context of the information society the Universe of Knowledge is recombining. In a rather traditional way one can distinguish "data", which are simply data recorded in a system (discrete, objective data, which record facts on the world and are easily structured, organized and transferred) and information which makes possible to transmit a message; thus Picasso passes a message through Guernica, and influences minds. According to T. H. Davenport and L. Prusak (1997), knowledge constitutes "a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories, but also in organizational routines, processes, practices, and norms" (p. xii).
In short, knowledge is a key factor of the firm competitiveness in the new economy based on information. Consequently, work and knowledge which were two relatively distinct values in the taylorist universe are mixing. Then training and the control of knowledge become a new stake. Acquired knowledge is becoming obsolete almost instantaneously and any individual must learn throughout his life. Taking into account the economic importance of the stakes, it is not astonishing to observe that, beyond the traditional places of knowledge, the Schools and the Universities, new training places are set up: companies develop training structures, such as for example Motorola University, Hewlett Packard or Sun University; one also sees, for example, Microsoft diffuse its own certification labels, equivalent to professional diplomas.

Form-Ami: a Pilot Project of the European Commission to Apply the "Socratic" Teaching Method

Technological progress thus modifies radically the relation between man and information and induces a considerable demand with respect to the education systems (See J. Richarson, 1996). *Virtues of a "socratic school"* resting on four pillars (on this topic see the publication of the European Commission, 1998): to learn how to know, to learn how to make, to learn how to live together, to learn how to be, must be accessible thanks to the use of ICT. Indeed, ICT must help the teachers to set up a teaching approach supporting not only training but also an hypothetico-deductive reasoning mode which will permit the learners to acquire an autonomy vis-a-vis the life events (see the document of the European Commission, 1998, p. 11). It is on this condition that the Knowledge Gap will be surmounted.

The Socratic Approach: a Process or "The Art to Be Confined"

> *"[...] research and knowledge are on the whole only reminiscence"*
> *PLATO, Menon, translation from Les Belles Lettres, tome III, 2, 1923*

Form Ami[1] is a pilot project of the European Commission with a view to promoting new university training courses in the specialized skills required by the information industries, through the socratic method and on the basis of an important consortium which includes academic institutions and information firms. *The socratic approach refers to the philosophy of education and to the teaching method presented by Plato. One will retain in particular the idea of the socratic "maïeutique", which is an art of obstetrician, and the conditions of the knowledge learning: the role of the teacher is that of a guide and the learner is responsible for his learning, which cannot be an accumulation of knowledge, but rather a search of knowledge by reminiscence.*

Within the framework of the Form-Ami project the socratic approach is implemented gradually, so that the students adapt to work as a group, by using more and more the multimedia tools and while trying more and more to solve by themselves the problems which they encounter. Thus two stages can be distinguished each one corresponding to a part of the teaching and to the realization of multimedia products: in the first stage all the students attend the same courses which give them the bases in art and mechanics of information; in the second stage the students follow specialized courses in the option which they have chosen: Security, Geographical Information Systems or multimedia Pedagogy. So they are very few in each option (between 5 and 12) and the follow-up work by the teachers is very effective. Obviously it is during the second stage that the socratic approach is the most applied, but the first stage is essential for a transition between a traditional teaching and a teaching based on the socratic approach with the intensive use of ICT.

Implementation of the Socratic Method for the Realization of Multimedia Products

For the academic year 2000-2001 among 500 European candidates finally 28 students obtained their diploma. The students were of 11 different nationalities; they represented largely the European Union and there were also non European students. Five multimedia products linked to the courses were realized on the following subjects: Theory of Information, Information market, Security, Geographical Information Systems, Pedagogy. The socratic method is in the heart of the teaching and of the realization of the multimedia products. From a pedagogical point of view the thread rests on a flexible process during which the students learn how to learn by working in group and with the multimedia tools. Of course, the students benefit from the help of the teachers, in particular from the content of research and work carried out for many years by the teachers-researchers-experts.

The principles of the implementation of the socratic method are best described by the process of realization of the multimedia product "pedagogy". For this multimedia product, realized during the second stage of the Form-Ami project, the socratic approach is reinforced, because the students are accustomed to work together, have better ability to use multimedia tools and also because of the number of students (only 12 students). So the teachers ask the students 12 questions to define progressively the outline of the multimedia product with the students. Questions are the guideline for the construction of the multimedia on line product and socratic exercises. The students define themselves 4 groups of 3 students and then work together; each group works on 4 questions, of course with the permanent help of different teachers (from the University of Aix-Marseille II -

---

[1] The Form-Ami backgrounds were defined by D. Deberghes, Administrateur Principal, European Commission, Information Society DG.

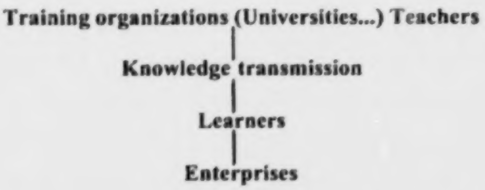
Université de la Méditerranée/EJCM -, the University of Tampere, the University of Koblenz-Landau and the CJD Maximiliansau). There is a high level of interactivity between the students and the teachers.

The Pedagogical and Knowledge Paradigm[2]

The Old Pedagogical Paradigm Confronted with the New Knowledge Diffusion Model

The old pedagogical paradigm can be defined as a knowledge push. In this framework, which is dominant since the beginning of the Gutenberg's Galaxy, teachers are the holders and have the monopoly of knowledge; they produce and diffuse knowledge with a specific place in the society.

Old pedagogical paradigm:
Knowledge push: teachers produce and diffuse knowledge

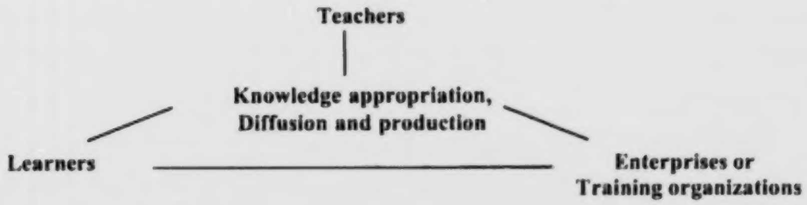


But today this old paradigm is questioned by changes which affect the universities. The whole university world will switch over tomorrow; according to P. Lévy (2000), "the universities will depend more and more exclusively on their customers (...) the students can now learn elsewhere (...) by shopping around in cyberspace where the on-line training offers are daily becoming more varied, more precise, better organized" (p. 95).

A Key for the Future: the New Pedagogical and Knowledge Mediation Paradigm

The Socratic approach is a new pedagogical model with the realization of multimedia on-line products: Form-Ami can be considered as a reference because it is perfectly adapted to the new information and knowledge society. *We define Form-Ami as a new interactive knowledge mediation paradigm: in the context of the new pedagogical paradigm teachers share knowledge and produce knowledge in collaboration with students and enterprises or training organizations.*

Interactive Knowledge
Teachers, learners and enterprises share, produce and diffuse knowledge



In this new interactive knowledge mediation paradigm the learning process becomes more and more a common construction and collaboration: "*Young people will be guiding their teachers to new kind of learning models*", predicts Mr. Juha Lipianen from Nokia (ED-MEDIA 2001, Hypermedia Laboratory, University of Tampere, June 2001). "*Knowledge is not delivered; it grows in unpredictable ways because learners move through this space according to their own needs, intentionally connected to others. Participation in this space makes it grow for you, over time and through your use and interaction.*"(P. Clifford and S. Friesen, 2001).

---

[2] source: P.-Y. Badillo, communications to different conferences and Final Form-Ami Report, July 2001.

Form-Ami is a useful reference because its pedagogical principle, defined about five years ago, anticipated the more up-to-date present research. According to D. Jonassen (2001) learning process is efficient if it is organized as a "solving problem" system; students are confronted to a problem and they have to solve it; the only professional legitimated goal of everybody is "problem solving" (decision making, modeling...). Form-Ami has been a rich pedagogical experiment because the students, of course with the help of the teachers, have had to solve problems: how to apply in practice the courses, how to produce a multimedia product, how to organize their practical training. Teachers have also to adapt their pedagogical approach and the educational organization to help the students to solve the problems. This new pedagogical paradigm is also described, for example, by B. Collis (2001): "What is our first aim? Learning from experiences, from one's own and from those in one organization, and building upon these experiences....".

Conclusion: From Digital Divide to Knowledge Leverage ?

The Socratic approach based on ICT permits the following results:

- *The Internet is a vast set of knowledge resources for the students: students often learn more effectively by discovery (constructivism) and by interaction (collaboration) than by lecture (direct traditional training).*
- *The students learn to work together, to be together and to collaborate in the context of different nationalities, different scientific backgrounds, but with a common objective and a common work: they learn to realize multimedia on-line products.*

But the new pedagogical model needs high investment in software, material and an intensive involvement of all the actors: very high intensive work of the learners (in Form-Ami: evening until 9.00 p.m. and some Saturdays, intense exchanges par e-mail), high investment of the teachers anywhere, anytime..., a lot of help by tutors. We have also to highlight the fact there is a danger: students can be hypnotized by new technologies; it is imperative to ask them to work on the content and to produce content through exercises.

In conclusion, with its Socratic organization Form-Ami has introduced a new pedagogical model. Form-Ami must be considered as a reference; this project was several years in advance and is fully adapted to the new pedagogical paradigm based on problem solving pedagogy and learners experience. However it is obvious, for cost reasons, that the generalization of the socratic method to standard courses is impossible. We will recommend to adopt this method for specializations for which today the needs are essential. *New technologies multiply the knowledge, learning and diffusion possibilities but also the cost; new technologies in pedagogy are submitted to the well known network effect: to launch a network is very expensive, then it is cheaper and cheaper. So, to break the digital divide thanks to new technology and new pedagogical method like the socratic approach will cost more and more at the beginning. Only later the fruits of these efforts will be available...*

CARA
A Constructivist Approach to E/C Resource Management and Administration

Michael Draper and Yves Perrin, – CERN, Geneva
(11 July 2002)

Abstract

Very often extremely valuable Education & Communication (E/C) material gets forgotten about and is buried in a drawer or computer file system once the event for which it was originally developed is over. CARA aims at making these resources, developed in various corners of CERN, wider known and available to as many people as possible. Our target audiences are the community of High Energy Particle (HEP) physicists but also high school teachers and the media. Such an approach saves both developer time by providing a source of inspiration and of documents and will help in gradually improving resource quality by building on what has been done before. CARA will be based on the CERN Document Server (CDS) which already hosts a large database relating to HEP containing more than 500,000 records. CDS also offers many related utilities including a document format converter and an automated information submission system. It uses the MARC based CDS metadata set extended for E/C material.

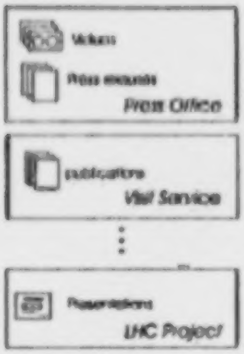
Why?

- re-usability of E/C material such as presentation slides, articles, brochures, leaflets, pieces of text, diagrams, photos, screen shots, web pages, video clips, animations, simulations, games, etc
- availability to other user communities (high school teachers, media, etc)
- automatic review of resource validity and characteristics.
- Reduce effort spent on duplication

Related benefits

- enlarge source of information and inspiration
- complement and/or improve quality of E/C material on a given topic by building on top of what already exists rather then re-inventing the wheel.

How?



Step #1

- identify potential sources of E/C material and types of available resources
- make inventory of existing resources

Step #2

Resource's metadata
Resources

- specify appropriate set of metadata to describe resources as fully as possible (identify the characteristics that potential users of the resource are likely to use when searching for resources and the characteristics that are useful to control the relevance of the resources over time)
- test relevance of this metadata with representatives of the targeted user communities on a few typical resources
- review specification of the metadata set accordingly

title:	CERN in 2 minutes, Du Big au Bang, Technology at CERN
location:	Press Office, Photo service, CMS
media type:	poster, film, leaflet, picture, presentation, etc
topic:	General information about CERN, Assembly of CMS detector
size (as seen by user):	23 pages, 800x600, 2m x 1.5m, 23mn
archive size:	47 KB, 3 video tapes
available formats:	Word, Illustrator, Power Point, JPEG
original event/context:	Open Day, Dalai-Lama visit, webcast
author(s) identification:	John Smith / CERN-EP
ownership:	CERN, Scientific American
creation date:	July 1975
last modification date:	May 1999
language:	English, Italian
interactivity level:	none, medium, high

correctness confidence : unknown, Press Office validated, DG validated

sub-topics / keywords : WWW, Tim Berners Lee

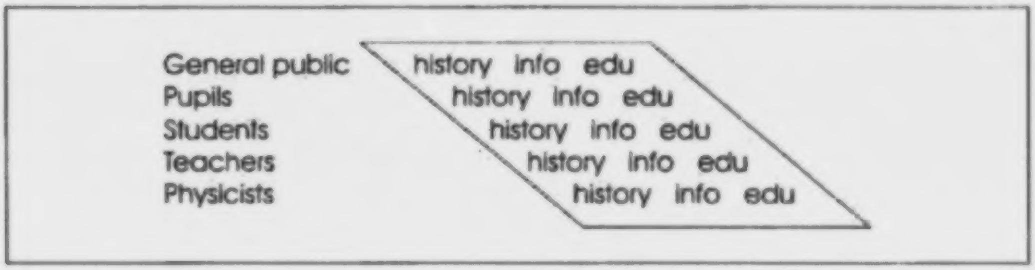
identified components : not analyzed, resource_id1, resource_id2

intended audience (level, age, etc): general public, physics students, pupils

estimated interest in year: edu/2001, info/1999, history/2000, etc

resource id : unique identifier of the resource within the system

next review year: 2003, 2005



Example of how the interest of an E/C resource might drift and survive over time for the community it was developed for and for other communities

Step #3 .

review all existing resources and for each of them:

- decide on the validity, redundancy, and usefulness
- if useful, record the metadata values corresponding to the resource

Hosting platform

- The CERN Document Server (CDS) is one of the major information sources for High Energy Physics. It containing link s to more than 500,000 resources (mostly scientific papers within the field of HEP, but also photos, videos and posters).
- The E/C resources will be catalogued in a separate "sub-base" inside CDS. Authors and/or system managers will use on-line submission procedures to add new material or modify existing resources.
- A customized, and easy-to-use (c.f. Google), user interface to ease E/C resource search, retrieval, submission as well as document format conversion.

publications

Criteria to measure system operation and maintenance quality

- how populated does the system get ?
- how accurate/up-to-date are hosted documents' metadata?
- how frequently is the system used?
- how much its use crosses CERN organization and targeted user communities boundaries?

Related issues

- responsibility of content (individual, group, project, lab) on expressed opinion, information sensitivity, data correctness, etc)
- copyright issues
- automatic signaling that metadata needs reviewing

Effects of Social Interaction on Learning in a Hybrid Model of an Online Course, Child Abuse Detection and Reporting

Brenda Dressler, Ph.D

Abstract: The paper is a report on the findings of the effect of social interaction on learning in this online course, Child Abuse Detection and Reporting. The course is delivered in the hybrid format, a mixture of asynchronous and synchronous models. A one-way analysis of variance was used to examine the scores on the questionnaires of 101participants for evidence of the effect of the chat on learning outcomes. Findings indicate no significant between the scores of Group I, the participants who completed the questionnaire before attending the chat and the scores of Group II, the participants who completed the questionnaire after attending the chat. Participants' evaluations of the course's interactivity reveal that the chat is viewed positively both by Groups I and II. Educators need to develop distance-learning models that encourage social interactivity.

Introduction

Given the tremendous growth of online courses educators and psychologists are investigating whether learning takes place in this format. Learning is defined as a "change in human disposition or capability that persists over a period of time and is not simply ascribable to processes of growth." (Gagne, 1985, p.2). A permanent change in knowledge, skill, attitude or interest or value develops from the learning experience. A fundamental aspect of learning is social interaction. Learning is accomplished when students are actively engaged (Leider & Jarvenpaa, 1993). Furthermore, educators who teach distance-learning courses concur that for these courses to be successful the student learner must be actively involved (Catchpole, 1993; Webster & Hackley, Dec. 1997). When a learner is actively involved learning is facilitated.

Adults learn through life experiences and then reflect on the knowledge gained and skills acquired. These are important factors in adult learning (Webster & Hackley, Dec.1997). Some educators of adult learners view successful learning as including "collaboration, interactivity, application, democracy, constructivist, and a sense of community" (Eastmond &Summer, 1998, p.34). In the Child Abuse online course, participants collaborate when they analyze their experience with witnessing or reporting suspected abuse/neglect and with the case studies imbedded in the course readings.

New York State Department of Education mandates a two-hour workshop on Child Abuse Detection and Reporting Course for teachers and other school personnel. The United Federation of Teachers (UFT), a state approved provider offers this class in two formats. One format is the traditional face-to-face classroom setting. The second format is an online course and is the focus of this research proposal. Two models of this online course, hybrid and asynchronous, has been ongoing for over five years. The hybrid course is the subject of this research paper.

The hybrid online course was offered each month from October 1996 through June 1998, excluding July and August to pre-service and in-service teachers, assistant principals, school secretaries and paraprofessionals. Participants are given two weeks to complete the assignments and access to AOL is required. The course consists of six parts: an introduction, four reading assignments that include six (6) questions, a myth and fact questionnaire consisting of 19 questions and a series of open-ended evaluation question and a synchronous one-hour chat. For purposes of this study, asynchronous learning is defined as learning that can take place in any location and at any time using a computer with Internet access. Synchronous learning is defined as learning that takes place at a distance but at the same time.

America Online's message boards are the electronic analog of the old familiar corkboard and pushpins. Participants post their answers and read messages at any time. Folders are posted on boards (the messages are inside the folder). The folders are organizational tools placed on the board to help you locate topics. The instructor asks additional questions, encourages class members to read and react to each other's responses. The instructor also posts questions based on participants' responses that appear on the electronic message board. Participants are required to write one or two sentences explaining their answers to the myth and fact questionnaire and e-mail their answers to the instructor. After the answers are received, the instructor then e-mails the correct answers to the individual participant. All required reading and responses are in the asynchronous format. Participants can complete their work when it is convenient for them. At the end of the two-week period participants are required to meet in a chat room for one-hour to discuss case studies in the reading assignments and in the newspapers and to respond to additional questions raised by the instructor. During the chat, participants collaborate and determine whether reasonable cause to suspect child abuse/neglect is present in these cases studies.

The Study

This research examines the following hypotheses regarding the distance learning hybrid model:
Hypothesis 1: Participants (Group II) who complete the myth and fact questionnaire after their participation in the interactive chat has significantly higher scores that those participants (Group I) who completed the myth and fact questionnaire before they participated in the interactive chat.
Hypothesis 2: Participants (Group II) who complete the myth and fact questionnaire after their participation in the interactive chat express greater levels of satisfaction than those participants (Group I) who complete the myth and fact questionnaire before they participated in the interactive chat.

Participants consist of new teachers who need to meet New York State Department of Education's requirement for certification and experienced teachers who need to take the course to be certified as an assistant principal and /or principal. These participants teach in the New York City public schools. Other school personnel such as paraprofessionals and school secretaries also take this course.

This study uses quantitative and qualitative data obtained during a one and one half-year period from 101 participants who have completed this hybrid online course. The quantitative information derives from the scores on the myth and fact questionnaire used to measure learning outcomes. Learning outcomes are operationalized by performance on the myth and fact questionnaire. The scores of the participants in Group I (n=71) who complete the myth and fact questionnaire before participating in the chat and the scores of the participants in Group II (n= 30) who complete the myth and fact questionnaire after participating in the chat are compared. A one-way analysis of variance was conducted to determine whether the mean scores of Group I and Group II were significantly different from each other.

In the Learning Hall (chat) The instructor asks questions such as, " how can the barriers to reporting suspected child abuse/neglect be removed?" and " do you know the name of the designated reporter and the members of the School Child Abuse Team?" and " do you agree or disagree that this case should be reported and explain why or why not?"

The qualitative data presented is taken from three courses, consists of open-ended evaluation questions. Participants are asked to evaluate the course. They are also asked whether the course was interactive and if they have any suggestions to improve the course. In addition, qualitative information from participants' interactive discussions with online classmates and with the instructor during the chat and at the electronic message board has been collected.

Findings

A one-way analysis of variance conducted to determine whether the mean scores of Group I and Group II were significantly different from each other indicated there was no significant difference between the two groups. Participants' responses to assigned questions posted on to the message board were brief, no more that a sentence or two. Answers were not well developed nor were they reflective. There was little response to the instructor's additional questions posted on the message board. Similarly, very few participants responded to each other's comments that were posted on the message board.

The following are comments made by Group I and Group II participants in three (3) classes in the evaluation section.

Group I: "Miss personal reactions and look forward to the chat; very efficient; reading others responses made it interactive; more convenient if my computer skills were better; looking forward to the interactive conference; look forward to chat room segment in which we will be able to "talk"at a more convers ation-like atmosphere; driving me crazy is the message board people are responding to me and then some one responding to them or me; suggest that it would be more interactive-maybe meet twice to discuss the topics at hand other than at the end of the class; incorporate the video into the course; turned out to be a course on learning to do more on the computer as well as the child abuse course; I couldn't have asked for more convenience; sometimes online learning is a much more social experience than traditional forms of distance learning, such as correspondence study; Info and materials were every bit as effective as taking the course in a classroom; In their hearts, I believe most teachers would report child abuse. With this information, they now have it in their heads as well; I am looking forward to "chatting" with other participants. Even though I cannot see or hear other participants, I still feel I have classmates. At this point I don't find this course to be interactive. However the day of the conference will be interactive."

Group II: "I enjoyed the online chat the most. It was interesting to see how we each interpret the information we had regarding child abuse. I believe there should be required refresher courses available. The course was great. I would love to take another course on the Internet; I did not find it to be very interactive for me since none of my questions were ever addressed on the conference chat. It was interactive enough because each person could post responses to other students' posts and because of the meeting in the Learning Hall. It was informative and fun using on-line technology to talk with colleagues."

Conclusions

There was no significant difference in the scores measuring learning outcomes of Group I and Group II. It may be that studies on distance learning should consider other aspects of student learning such as what did they learn, did they learn to analyze and did they learn to be critical about the subject matter, is there student participation and collaboration and was interactivity encourage by the instructor. A model that encourages social interactivity needs to be developed for the online course. Also, the extent to which students' technological abilities impact learning and social interactivity in an online class needs to be investigated.

Generally, participants did not click on to the message board to communicate with other classmates. Their answers to the six questions were brief. This was probably due to limited experience with technology as indicated in their evaluations.

In the evaluations, the chat is viewed positively both by Groups I and II. Evaluations indicate that Group II felt connected to each other. Group I looked forward to the chat. Success in the chat room however, depended on good typing skills to keep up with the discussion. Furthermore, if the class had too many students then discussions in the chat room were difficult. The ideal size consisted of 10 students. The chat did give the students the opportunity to collaborate on various cases and situations in the schools.

Estimating Development Time for E-Learning Programs

Mark Eaton
Cerner Virtual University
Cerner Corporation
E-mail: meaton@cerner.com

Abstract: Project managers and instructional designers face two challenges with every new e-learning project engagement - accurately scoping the project and then controlling it. The former often involves undisciplined practices. The latter is made more difficult because of it. Accurately estimating projects requires detailed analysis that is rarely available prior to signing agreements and contracts. The success or failure of a project is often determined by the quality of estimations since they tend to set client expectations. This paper recommends using estimators that are designed for specific types of e-learning solutions to improve quality and accuracy of scoping. Estimators provide a foundation for terms of reference, project scope, and help set client expectations. There are four steps in developing an estimator – define a learning event, define levels of interaction, identify development activities, and create the estimating matrix.

Methods for Scoping Projects

Project managers face two challenges - accurately scoping the project and then staying within scope. Since scoping sets client expectations, the success or failure of a project is often determined right from the beginning by the quality of these estimations.

There are three basics approaches in estimating projects for fixed fee services. The first is a simple gross estimate with a percentage of time added on for risks. It is quick, but not accurate and doesn't help when there are misunderstandings about the requirements.

The second method is to use a ratio of development time to learning time. Example: it takes 600 hours to develop 1 hour of learning; therefore, a two-hour e-learning program will take 1200 hours to develop.

I use ratios to analyze internal changes to development tools and processes for a specific type of e-learning program. With the exception of the changes, all factors remain the same and it is helpful to measure what effect, if any, these internal changes have on the development timeline. Ratios work when assessing these changes if they are internal to one program or activity.

It is very risky, however, to use ratios in a proposal that involves new technology or for comparing different solutions. Consider two proposed solutions where one is a simple slide presentation and the other has interactive practice exercises. The ratio for one will be significantly less than the other and the reason for the differences is not always as obvious as it is in this example. Ravet & Layte (1997) recognize this and suggest splitting ratios into components like knowledge acquisition, practice, and testing.

The third method is to use a tailored estimator for the specific type of e-learning solution that is proposed. More and more e-Learning content developers are using various types of estimators.

In this paper, we look at the steps to develop an estimator – define a learning event, define levels of interaction, identify development activities, and create the estimating matrix. The estimator is the best method to scope projects because it becomes the terms of reference and clearly communicates types of learning events and levels of interaction.

Process in Developing an Estimator

Step One: Define a Learning Event

It is usually necessary to begin by evaluating the type of analyses the designer will use in the instructional design approach. For example, Task Analysis is a process to identify target and enabling objectives (Gagne, Briggs, & Wager 1992). The analysis can be used to identify an event profile and course map. From this, designers can identify the lowest level of granularity.

This lowest level in the course hierarchy is a recognizable learning event that can be added, removed, or modified somewhat independently within the course. It is consider portable if it meets this criteria and it needs to be defined to help set client expectations. For example,

> A learning event is considered the lowest portable learning object and is an independent set of tasks that collectively form a complete piece of instruction. It is a short piece of instruction that takes only a few minutes to complete and no more than 10 minutes.

The next step is to classify learning events into various levels of interaction. Ten minutes of instruction that is almost entirely text-based is much different than ten minutes of instruction that includes games, even though both may take the same amount of time to complete.

Step Two: Define Levels of Interaction

There are many classification systems that are available to classify levels of interaction. Schwier (1992) proposes taxonomy of interactions in terms of the user's cognitive engagement. He evaluates interaction on three levels – reactive, proactive, and mutual interaction.

More recent classifications include defining the interaction between the actors – students, instructors, and the system or program (Wagner, E. D. 1998, Sook K. S. & Bonk, Curt J. 1998). Others describe interaction from the developer's perspective and the media components – graphics, text, animations, simolations, user inter-face controls, etc. (Bixler, B. & Spotts, J. 1998, Sims, R. 1997).

I use the classification scale in Table 1. It has six levels to describe types of learning events and how users react to them.

Level	Type	Description
1	Single Document	Characterized as a single document like on-line reference manuals. Controls are limited to scrolling or clicking objects for sequential or non-sequential hypertext navigation within the document.
2	Web Document	Multiple documents. Involves additional branching for specific instructional support (Schaefermeyer, 1990).
3	Multimedia	Includes text, graphics, animation, and audio. User can play, pause, rewind, and advance through the animations.
4	One-True-Path (OTP) Simulations	Simulates basic features of the system or environment. OTPs are usually linear. The prominent feature is that triggers are embedded within the simulation so that navigation occurs by interacting with the simulation.
5	Multiple-True-Path (MTP) Simulations	Limited exploration. MTPs have more effective hands-on realistic experiences than level-4 OTP programs. Multiple parallel pathways exist, but are limited or controlled.
6	Scenario Simulations	The best example of this is an aircraft flight simulator. The learning program not only has the look and feel of the actual system, but also uses underlying algorithms that fully describe the real world system. Great for what-if scenarios.

Table 1: Classification by Levels of Interaction

Step Three: Identify the Design and Development Activities in the Construction of a Learning Event

Designers identify activities that are involved in designing, developing, and producing learning events. These activities are fairly common across e-learning solutions. Table 2 gives a sample of activities.

Activity	Description
Design	Creating the training scenario - writing assignment text or directions, writing any learning support messages that may be required, identifying and describing the scenes or pages, and identifying the conditions that will let the student progress between tasks and events. Output is a detail design document or storyboard.
Database Development	Entering data into the data structure. May include data entry into an actual database or creating other data sources that the event will utilize.
Authoring	Developing learning events using tools or authoring systems that do not require programming.
Programming	Actual programming using high-level languages or scripting languages.
Integration	Integrating tasks together into learning events and integrating events into lessons. Setting triggers for navigation and integrating all the learning support tools the end-user will need.
Testing	Testing - following the development of each learning event or after all learning events have been integrated. Estimations take into account the number of iterations that will be required between development and testing.

Table 2: Development Activities

Step Four: Create the Estimation Matrix

It is here that you document approximate times required for the various activities in developing a learning event. Table 3 shows a sample matrix. Notice that it takes approximately 7 hours to build a level-1 learning event and 110 hours to build a level-6 learning event. Thus the matrix accounts for variations in each activity among the various types (interaction levels) of learning events.

Levels Activities	1: Document	2: Web Document	3: Multimedia	4: OTP Simulation	5: MTP Simulation	6: Scenario Simulation
Design	2	3.5	5	6	12	20
Database	.2	.2	1	4	8	20
Authoring	3	5	7	7	8	15
Programming	0	0	2	4	6	30
Integration	1	1	3	3	6	10
Testing	1	1	3	3	6	15
Total Time	**7.2**	**10.7**	**21**	**27**	**46**	**110**

Table 3: Estimation Matrix

Using the Estimator

Table 4 shows the output of the estimator to scope a proposal. In this example, a learning program will be designed to develop skills on using a word processor. The first column documents the proposed learning events. The second column identifies the level of interaction that is required for each event. The last column is the estimated time to manage the activity based on the estimating matrix in Table 3.

Proposed Learning Events	Level	Development Time
Home Page	1	7.2

Course Overview & Getting Started	2	10.7
Opening the Word Processor	3	21
Creating a New Document	4	27
Enter Text in the Document	5	46
Running Spell Check	5	46
Saving Changes to the Document	5	46
Open and Modify an Existing Document	5	46
Copy and Paste	5	46
Adding Tables and Graphics	5	46
Closing a Document and Exit	5	46
Summary/Review	2	10.7
Total Development		**398.6**

Table 4: Sample Course Plan with Learning Events, Levels, and Estimates

There are several advantages to using this approach. First, it provides scope of the project. At a consulting rate of $120 per hour and approximately 400 hours to develop, the fee is over $47,000. If the client needs the project closer to $40,000, the number of learning events or the interactions can be adjusted to bring the project into range.

Secondly, it sets client expectations right from the start. Any changes (interactions or number of learning events) can be managed as out-of-scope as opposed to absorbing the changes within the fee and timeline of the arrangement.

Finally, estimations are *distributed* across the learning events. It is much simpler to add, remove, or classify learning events instead of re-scoping the entire project each time there is a change.

SPIDER TUTORING SYSTEM For TEACHING COMPUTER PROGRAMMING LANGUAGES

Mahmoud M. El-Khouly
Mathematics Department, Faculty of Science, Helwan University, Egypt.
melkhouly@yahoo.com

Abstract: This paper presents a spider tutoring system (STS) for teaching computer programming languages through WWW. In this version, spider technique have been used to update the databases used by the blackboard hosted at the tutoring agent (TA) server, with blackboard module a student can exchange his expertise with other students. Due to overwhelming size and growth rate of Internet, spider's discovery had been restricted to direct discovery technique only.

Introduction

Learning one of the computer languages today, is essential for students in both undergraduate and graduate levels. However, when I asked around 300 faculty students about their knowledge about the computer, I found that they almost use it as a tool for typewriting or games. There are many reasons for not learning computer programming languages (e.g. economical reasons, the lack of good instructors, geographical distance, etc…). Egyptian government offered a free internet from beginning of the year 2002, therefore accessing the internet costs only 0.2 $/hour (previous cost was 2$/hour) which gives us a good support to provide some web-based tutoring system for teaching computer programming languages.

The movement toward client-server applications began in the late 1980s and so in many organizations there are already many server applications with well-structured APIs for RPC or IPC access by a client. However, in many cases the backend server is a relatively standard database monitor, which provides no logic or protocol specific to the current application. The emergence of network computing, where the client side of the application logic is provided by JAVA applets that are downloaded at runtime to a Web browser, offers a new opportunity for constructing the agent-equivalent of a Web browser (Alper, 1997). With the WWW as an educational platform, it will be feasible for the students to access the multimedia courseware with general-purpose browsers. No special tools are required to start learning. For the courseware provider, it is not necessary to worry about the distribution and maintenance of the copies of the courseware but they just take care of the original on their server (Kiyoshi et al., 1997).

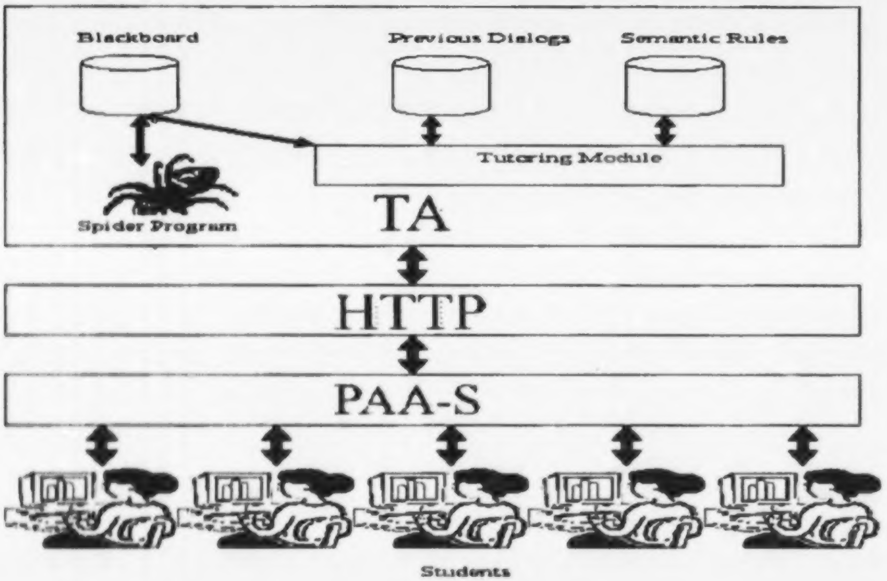

Figure (1): STS system

Lewis Johnson (Lewis Johnson, et al., 1997) support interaction with teachers and students through their project ADE, using off-the-shelf whiteboard and teleconferencing tools. But this required both teachers and students to be on-line.

M.M. El-Khouly, et.al. (2000), presented an expert tutoring system (E-TCL) for teaching computer programming languages through WWW. In this paper, I extend the features of that system to include spider technique. The most common application for spiders is creating and updating the databases used by search engines.

The proposed system consists of two agents representing a server-clients relationship, tutoring agent (TA) as a "server", and personal assistant agent for students (PAA-S) as a "clients". The PAA-S can communicate with TA through WWW to retrieve the tutoring dialog of the command(s) that a student wants to practice, and to access the experiences of other students in blackboard module (as shown in (fig. 1)).

Pedagogical Design

When the structural computer language course content was analyzed, it was clear that the subject matter was topical in nature, and could be organized into a small number of reasonably self-contained modules.

The following form the central core of any procedural computer language curriculum.

- Input/Output statement
- Conditional statement
- Loop
- Array
- Function
- Structure
- Input/Output files

The following was adopted as a model for each module:

1. Introduction: here the basic ideas and concepts were presented. The major goal was the motivation of the central idea of each module.
2. Syntax section: basic understanding of the syntax of the command, and ay examples about different forms. After all, a series of multiple choice questions are presented. The student must answer these before progressing to the next activity.
3. Procedural section: algorithmic understanding to reinforce connecting statements together to build more lines of programs pieces.
4. Strategic section: problem solving: after the student is familiar with the basic concepts in the module, more complicated multi-step questions are presented. This reinforces problem solving strategy.
5. practice exercises: at the end of the activities in each module, a series of exercises is presented to the student. Each problem is graded and the student is told whether he/she is correct or not.
6. Graded quiz: after the practice exercises, a series of questions is given to the student. They focus on the procedural and strategic components of the module.

Tutoring Agent

TA contains tutoring module, previous dialogs database, semantic rules base, spider program, and blackboard database.

Spider Program

A spider program creates a database by scanning the Internet and updates by continually scanning the WWW. To index a site, a spider must crawl it, meaning it must find all the pages the site's home page links to. Spiders add the pages they crawl to the search engine's database – a task that can be performed in several ways. Some spiders add every word of a web page to the database index. While others include only words listed in special <Meta> tags embedded in a page. Some spiders are being developed to execute multimedia-oriented searches or the automatic assignment of categories based on content.

Two basic techniques of discovering exist: blind discovery and directed discovery.

- blind discovery entails simply trying to access every IP address is existence
- direct discovery -which is significantly faster than blind discovery-entails scanning a list of known domains to see which ones are still on line and responsive. A list can be constructed or acquired in a number of different ways, but the most extensive approach is to start with the list of top-level domains (TLDs). *Directed discovery isn't necessarily limited to the original list of sites: as the* spiders crawls each page, it's bound to discover new links. By adding new links to the database of site, more and more pages get introduced to the system (David Pallmann 1999).

Personal Assistant Agent for Students

The personal assistant agent for students (PAA-S) consists of three components, student model, tutoring module and user interface module.

Conclusion

In this paper, STS system had been presented for teaching computer languages. STS consists of two agents, tutoring agent, and personal assistant agent for students. They communicate with each other as client-server through WWW. This allows the system to communicate with other agents to exchange semantic rules and tutoring text for different languages. The spider technique had been used in PAA-S. Such that the blackboard modules hosted at TA, can be updated continually to see whether the student is on-line or off-line and therefore checking whether he/she will contribute to the current inquiry or not? This will safe time for waiting students who are off-line.

Institution: National Autonomous University of México

Abstract

During this presentation, it will be demonstrated how the Academic Computer Center (at the National University of México) is helping their face-to-face teachers to develop online content for online courses.

Introduction

The Academic Computer Center is nationally recognized as a leader in computers and telecommunications technology. Among other things, it is responsible for bringing computers and telecommunications training to the Mexican population. The Academic Computer Center has over 200 different courses and 300 face-to-face teachers but by the end of the year 2001, only three online courses formed part of the course catalogue. How can we expand our online courses offering? How can we help teachers modify and make their notes more accesible for an online course? How can they experience an online lesson?

In order to answer these questions is that a semi-online workshop for planning and developing online courseware has been designed.

The workshop consists of two modules, the first of them (over three weeks) is to be given through the Internet and the second one (over six weeks) is to be given in a classroom in two-hour sessions per week.

Content

The Semi-online workshop for planning and developing online courseware was designed for those teachers interested in developing online courses. Because we think teachers are the content experts and that they do not necessarily need to know about programming, designing or administering a server, the only pre-requisites that we required the teachers to have prior to the workshop were:

1. Managing the Windows interface
2. Internet connection
3. Being able to use a word processor
4. Have email access
5. Have already selected the coursware's content

The workshop consists of two modules. The first one is theoretical and when finished, the student will be able to understand the significance of the instructional design. The student will be introduced to the distance education concept and the technologies for delivering it.

The first module is based totally on the Internet; forum discussions, handing-in assignments, evaluating online products and suggested readings are some of the activities proposed for this module. The student (in this case, the teacher) faces the situation that his or her own students will also be facing; loneliness, motivation, feedback and evaluation are four basic concepts that are easily explained with words but are difficult to achieve with this media. In order to help them face this issues we worked on each of them, as follows:

Loneliness We regularly send emails to the students; either to tell them we received their homeworks, o to ask them about their feelings being in the course.
Motivation. During the discussions on the forum, we tried to collect some of the students' comments or works, telling the rest of the group about an interesting view or work.

Feedback. Because students are expecting to know if they are doing well in the course, it is important to tell them about their performance as well asto make them feel that the tutor is following the discussions, by asking questions and directing the discussion.

Evaluation. Evaluating a person that is at a distance is difficult, first of all, because we are never sure who is behind the computer. The way we have dealt with this question is by assigning several activities along the course in which students have to work constantly. This system has helped us to, not enhance a proactive interaction among students, but also brings the opportunity to construct related and more complex activitites as the course advances.

During the case of the second module, students are basically developing their courseware content. Face-to-face sessions are used for supervising, consulting and sharing ideas and experiences within the group. A special content delivery system was developed for students in order to help them construct and see their course; they are also able to view the other on going projects.

In México, most teachers do not have any distance education experience; neither as students nor asfacilitators. It is difficult for them to adapt and interact freely at their first online course, and because we know they have good ideas, questions and proposals for teaching we decided that, for the second module, face-to-face sessions would be better than online assistance.

Development

An interdisciplinary group developed the workshop. A graphic designer, two instructional designers, a media integrator, a system developer and an interface designer were integrated into the team.

Planning: We consider that there are two basic problems to solve when someone decides to transfer a faco-to-face course to an online one: the content's development and the role the teacher must assume because of the technology. We decided to concentrate on the first problem and help teachers identifying differences, advantages and disadvantages of the Internet for the delivery of information. The workshop's coordinator and the two instructional designers worked on this stage.

Content Selection: Because an online facilitator teaches at a distance, it is important to be aware of this significance. That is why the first two subjects to be overviewed in the workshop are Distance Education and Distance Education Delivery Technologies. The next subject is Internet and online education, concentrating on online courses. The following subjects deal with independent study, instructional design, and web content design usability concepts. All these subjects are taught through the Internet and students have plenty of activities to do. At the end, students are asked to develop their course content and face-to-face sessions are used to show each person's progress and to discuss ideas and doubts. Teachers are asked to put their materials on a server, using a system and an interface designed specially for them. People participating in this stage are the workshop's coordinator, the instructional designers and the interface designer.

Development: Once the program was decided and the content selected, it was time to develop the workshop's site (web pages for the online module and the course delivery system to be used during the second module). The whole team participates at this stage.

Evaluation: When both web sites were finished (the online course and the course delivering system for the teachers), functionality, usability and learning evaluations were applied. We invited teachers to participate on the 6-week workshop. Twelve teachers attended the workshop but only nine finished it. We handed out a questionnaire to those persons who abandoned the course for feedback, as well as those who did finished it.

The main comments we received about the online module were:

- the agenda wasn't very clear to people; they didn't understand how the course content and activities were distributed along the six weeks
- people needed a printable version of the documents
- people thought it would be important to have an a students' space so they could post personal information and thus to get better acquainted with each other
- some notes should be improved by adding specific references

For the course delivery system, they told us:

- they had the possibility of sending 'pdf' documents
- they could see other people's courses
- they wanted to use our delivery course system in the future for their courses

For the didactic aspects, they all agreed:

- time was top limited in order to reach the course's objective
- there were too many activities
- face-to-face assessments could be improved by discussing and analyzing more fully everyone's progress
- they wanted assessments after the workshop was completed

Results

- Four online computer courses were developed as a result of the workshop and three of them are now part of the online course catalogue.
- The workshop site was redesigned and the teacher's notes were improved.
- The workshop now lasts 9 weeks (three to be attended by Internet and 6 face-to-face sessions).
- The workshop was included on the online course catalogue and promoted through the university's web page and newspaper.
- 24 students enrolled in the following workshop.

Abstract

This paper presents a tool called iQUIZ that tries to facilitate composing, distributing and correcting online quizzes for different groups of students in a given course. iQUIZ is a client-server TCP/IP-based application; the server can be used by educators and/or organizations to compose and host online quizzes. The client application will be used by students or any other party (e.g., customers) solving the quiz. iQUIZ is characterized by its ease to use graphical user interface and its high degree security features.

1. Introduction

University teachers spend a lot of time differentiating and correcting exercises and quizzes and posting student marks on the web. They may do it using a web-based learning system like WebCT or just by typing the information using a standard word /and or HTML editor. On the other hand, and based on our own observations, students don't express much interest in assisting to labs or discussion groups. This work tries to facilitate composing, distributing and correcting online quizzes for different groups of students in a given course. We want to give the students a good reason to assist to labs or discussion groups.

2. Architecture

iQUIZ is a client-server application developed in Visual C++ using MFC. The client sends its ClientID and Password to the server for validation, if it is the first time the server will create an account for that verified client (there is an authorization from the server administrator to create an account for that new user by having registered the student number for example so that not all students can create accounts).

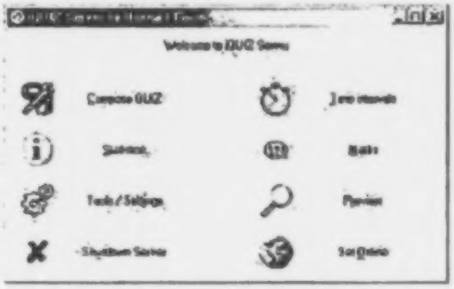

Figure 1. User interface of the iQuiz server

The server hosts the quizzes and sends the quiz version corresponding to the client ID. The communications take place in real time, each time the client answers a question, the answer is automatically sent to the server and stored locally. The communication socket is destroyed when the quiz is over.

2.1 Security issues

- Digital signature:
    - Both the server and the client are digitally signed to prevent malicious users from modifying the code or resources of our application. Unlike Java applets that can be decompiled and modified.
- Encryption:
    - All communications between the server and its clients are encrypted.
    - Local quizzes are stored on disk but using a very strong encryption algorithm(Blowfish 128 bit encryption for example)
    - Data stored on the client's side for high availability purposes are also encrypted using the same algorithm (Blowfish 128 bit).
- Semaphores:

BEST COPY AVAILABLE

- To allow only 1 client application to be ran on a single computer by a single user, we create semaphore objects in memory.

2.2 Upload

iQUIZ can communicate with an FTP server using the File Transfer Protocol to upload files to that server. A feature of iQUIZ is automatic marks upload at a given time interval, which will be discussed in the next Section.

3. Implementation / Easy to use UI

Figure 1 represents the user interface of the server. It consists of 8 items which can be described as follow:

3.1 A friendly, easy to use interface to compose the quiz

As can be seen in Figure 2, the educator can compose a question with a maximum of 5 multiple answers. She/He can also specify the difficulty level of this question, and has the option to give a maximum amount of time the student is allowed to have in order to answer the question. In the Scenario field the educator can specify several consecutive questions on a subject which the student can read in a popup window. The total questions field shows the number of already composed questions with their difficulty level respectively.

3.5 Tools/ settings

Figure 5 displays the various features of the iQUIZ tool: the ability to load with Windows on startup. The quiz can differ from one student to another when Randomize is checked so even in the same group; the order of the questions in the quiz will be based on the student's number. The educator does not need any more to worry about posting marks; iQUIZ will automatically do it for her/him and on regular basis if she/he wishes. Marks are posted via FTP with a single click. The educator can also arrange students in groups and manage them with ease. The iQUIZ server auto-corrects the quiz, put the marks on the educator's desktop and uploads them to the desired FTP site.

Generate
Done

☐ Randomize questions based on student number
☐ Auto-post marks every 0 minutes
☐ Use student groups: ex: AB AC
☐ Start with Windows

Figure 5. Quiz settings

The educator can also specify how many question of each type (easy, medium, hard or difficult) the quiz should contain and how many different versions of the quiz should be generated (therefore we will have different quizzes for different students in the same group). She/he can also have 1 different version generated for each group.

BEST COPY AVAILABLE

3.6 Preview

The educator can preview what each generated quiz contains before hosting the quiz and setting the server online. This is to ensure that everything will be done as planned by the educator and give her/him the comfort and more control over the quiz. This feature is based on the well known concept of what you see is what you get (WYSIWYG).

3.7 Set online

This button sets the server online and makes it ready to accept client connections. Note that the educator can set predefined time intervals and iQUIZ will go online and offline automatically. With the ability to startup with Windows, the educator doesn't have to remember to execute the iQUIZ tool each time she/he turns on her/his computer. After the server is set online, this buttons turns into a Set offline button to tell the server to break all connections and stop accepting new connections.

3.8 Shut down server

This button shuts down all communications and terminates the application.

4. Evaluation

The system has been tested by two educators, who generated a number of quizzes for their students. They were very satisfied with the easy to use user interface and the lack of complexity. At the same time we did a network communication in order to study the number of users (students) the system can simultaneously support. Our simulation showed that we could support about 300 users without decreasing the response time from the server. This is due to the fact that we are using TCP/IP communication protocol and therefore we could support virtually thousands of users (every user will be given a special port). Practically and based on our prior experience [elsaddik2001] the server last will increase linearly with the increasing number of users.

5. Conclusion and future work

After the success of our test simulation we are planning to use it in fall 2002 (Course ELG5121 Multimedia communications) at University of Ottawa. We are also planning to add some other features, among others:

- Load several quizzes at once and have a specialized tool to compose the quizzes separating the communication part from the composition part.
- Remote control the server from another computer.
- Email support: we want to be able to send congratulation emails to the students with the highest achievements!

We also plan to use XML-based specification and develop a Java version of this project to ease deployment and allow usage on different operating systems.

A DISTRIBUTED WEB-BASED K-12 MANAGEMENT SYSTEM

JOÃO FERREIRA, ALBERTO SILVA, RUI AZEVEDO, GONÇALO BORRÊGA

ISEL / DEI-IST-UTL / INESC-ID LISBOA

(jferreira@deec.isel.ipl.pt, alberto.silva@acm.org)

Abstract: The project "Rent@School - Bringing the Future to the Education" is a research effort to study and prototype information system architectures to support, standardize, and facilitate the management of K12 schools at a national scale. It looks for the sharing and dissemination of relevant information among different stakeholders, based on the ASP model and also on a novel architecture, which we called "distributed and multi-instance web architecture". This architecture means that beyond the existence of a unique central/national Rent@School instance, multiple Rent@School instances can be installed at local/regional scale, in a way that autonomy, performance and flexibility of all the system can be improved. This issue is introduced and discussed in this paper from two complementary perspectives: from the organizational and management information systems perspective; and from the integration and large-scale interoperability.

1 Introduction

Education is considered by modern societies to be one of the most important and strategic factors that contributes for the development, wealth creation and solidarity of any Nation [1,5]. In this context, Rent@School (RS) is a research project where we will propose and discuss organizational and information system architectures to support, standardize, and facilitate the management of K-12 (from kinder garden till 12th year) schools at a national scale, as well as, the sharing and dissemination of relevant information among the different stakeholders, such as students, teachers, schools' administrators, parents, and Ministry of Education' support and technical employees. This project is particularly oriented by the Portuguese educational public system (the educational private subsystem has some facets and requirements that we deliberately did not consider).

The RS project is being developed in the context of the ISG (Information System Group of INESC-ID) where we are interested on two main research topics. First, to study organizational systems, architectures and patterns, in particular those with complex, dynamic and distributed features which can be found in different areas of the economy and society, such as public administration, education, transports, logistics, or tourism. Second, to study the best information systems architectures and patterns to support the referred systems, following a technological perspective.

RS is based on the ASP (application service provider) model, however, adopting a novel architecture, which we called "distributed and multi-instance web architecture". This architecture means that beyond the existence of a unique central/national RS instance, multiple RS instances can be installed at local/regional scale, in a way that autonomy, performance and flexibility of all the system can be improved. This issue is particularly interesting and novel and it is introduced and discussed in this paper from two complementary perspectives. First, following the organizational and management information systems perspective. Second, following a more technical perspective, in particular regarding issues of application integration and large-scale interoperability based on the web services concepts.

The main novel contributes of this paper can be summarize in three points. First, we propose and discuss the interest of an information system that can support, standardize, and facilitate the management of K-12 schools at a national scale. Second, the proposed architecture is not restricted by itself to the classic and central ASP model because it allows the installation and configuration of multiple instances promoting, in that way, the autonomy, flexibility and performance of the overall system. Third, we propose and discuss the importance to develop this kind of system with public and open interfaces, promoting integration and large-scale interoperability among different systems.

This paper is organized in 6 sections; including this one (Section 1) that describes the context, the motivation and its main contributes. Section 2 describes briefly the Portuguese educational system, and in particular the subsystem of public K-12 schools. Section 3 identifies the most relevant (functional and non-functional) requirements that the RS design and prototype should take into account. Section 4 presents and discusses issues related to the information system architectures that support the RS, as well as, related to the application integration and large-scale interoperability. Finally, Section 6 refers some considerations related the future work and the research aims.

2 Portuguese Educational System

The educational system in Portugal, like in most of the developed countries, is organized in classical training and/or professional levels. The following educational levels exist in Portugal: pre-primary; primary - 1st cycle (1st to 4th years); 2nd cycle (5th to 9th years); secondary-high school (different areas, like classical, artistic and professional are available); and higher education (divided in University and Polytechnic). The Portuguese educational system is available, at all different levels, either Public or Private. Quoting the official source INE regarding year 2000/2001, the education K-12 has a total population of 1.261.603 students (approximately 12% of the Portuguese population) distributed by 16.984 educational facilities or schools.

The RS formulates his proposal for all K-12 schools and other performers acting in the Public educational sub-system. In Portugal this sub-system in organized as shown in figure 1.

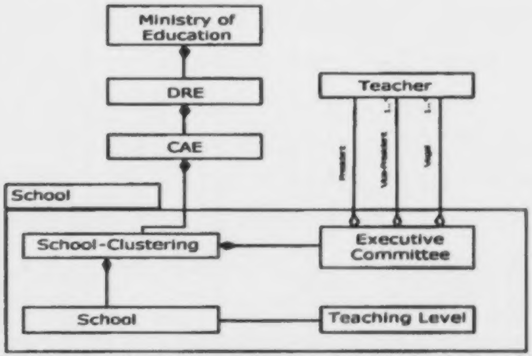

Figure 1: Organization of Portuguese educational system for the first degrees levels.

Schools are the elementary unit of educational activities. For financial reasons, regarding the level of performance on administrative tasks, the schools are organized in groups, called "school-clustering" or just "clusters". Each school can provide and manage more than one educational level. The main objective of the cluster structure is the possibility of different schools sharing a package of resources (e.g., human, technical and others) obtaining a better global costs system performance. The Ministry of Education is responsible for the planning, promotion, follow up and evaluate the available resources for the public education sub-system. This sub-system is divided in various responsibility levels namely the Educational Regional Delegations (DRE) as 1st hierarchical level. As the 2nd level there is Educational Supporting Centers (CAE). Each school is associated to a certain CAE (and therefore to a certain DRE), besides the cluster they belong to.

3 General Requirements of Rent@School

In this section we summarize the main requirements that should be supported by the RS system. Namely, we identify two major groups of requirements: functional requirements, that match the use cases; and non-functional requirements, that match the common needs that the system should satisfy independently of specific functionalities.

3.1 Functional Requirements

RS provides a personalized service for different types of stakeholders. It can be seen as a "multifaceted portal for the Portuguese K-12 teaching system", becoming the personalized portal for schools, students, parents, teachers and administratives. We identify the main functionalities of the RS based on these stakeholders: **Administrator, MinistryOfEducation-User, School-SuperUser, School-Executive, School-Administrative, School-ClassDirector, Student, Teacher and Parent.**

Like other ASP applications, the responsibilities of each user are based on the chained delegation approach and profile management. The "Administrator" actor is the user with more power on the RS, in particular she can manage schools, and for each school she can manage the School-SuperUser accounts. The "School-SuperUser" actor is responsible for the configuration of school data and for the management of other school users, such as "School-Executive" or "School-Administrative" that performs very important roles in school administration and management.

"Student", "Teacher" and "Parent" are not school-level users; they are global-level users. This means that students and teachers should have a global identification, independently of the current school association. The same should be verified for parents: independently of the number of students associated, and the different school registrations, the parent should not have to manage various system user-accounts to access the data of their dependent students.

This issue of global identification of students, teachers and parents (independently of the school and the academic year) is novel and we expect that it can bring a real impact in the quality level regarding the management of the education system. Namely, it can bring the following contributes (1) a better and simple way to record history and curriculum of the different actors; (2) a more integrated and personalized service can make possible a simpler, direct and easier interaction; and (3) a significant simplification in the administrative processes such as school registrations, student transfers and evaluation.

3.2 Non-Functional Requirements

Non-functional requirements have to do with general aspects of the system like performance, robustness, liability, distribution, security, integration with the Internet and opening to standards. We identify in this project the following non-functional requirements: **Usability, Performance and scalability, Local and access type independency, Privacy and confidentiality, Openness and integration with other systems, Messages and alerts delivered through multiple channels.**.

4 Rent@School Architecture

In this section we discuss important topics related the RS architecture, a well as its mechanisms to support open-interface and interoperate with other systems.

4.1 Distributed Single Instance Architecture

In order to satisfy the general requirements identified in Section 3, in particular the non-functional requirement of "local and access type independency", RS should have necessarily to be developed based on a web information systems architecture.

RS follows the typical ASP model, in a way that it provides several functionalities to a selected range of actors that have previously subscribed to the system. Additionally, those functionalities are supported by a complex information system, kept and managed by a credentialed entity and responsible by supporting a number of quality of service parameters, such as performance, security, privacy and confidentiality of data, and liability. This entity – the RS manager – can be a telecommunications operator and/or an institute related to the Ministry of Education.

The main advantages present in this model resides in the fact that the participant actors never have to be worry about technological issues, such as: installation, licensing and configuration of applications; data quality; backups; availability of computing systems; or even issues concerning the updating of new versions. On the other hand, this model requires that the support computing architecture provides extremely large performance and scalability levels (thinking on the huge number of potential users), and doesn't allow for an eventual decentralization and autonomy of the information systems at the regions level (e.g, at DRE and CAE level) or even at the school level.

4.2 Distributed Multiple Instance Architecture

In order to solve the problems referred on the previous paragraph, we propose (to be developed in the second phase of the project) a novel architecture based on multiple instances of RS.

This architecture consists in multiple instances of RS, which can be installed at different management levels of the public education system hierarchy. For example (without considered the central/national level): at regional level (e.g., at all DRE); at school-clustering level; or even in a mixed way, such as at the central level and at the school-clustering level for the ones that may have technical conditions to operate one RS instance.

Although there are some variants in the way the deployment and configuration of the several instances are performed, we assume in this article for the sake of simplicity, that the various instances would be installed at the school-clustering and therefore, every school belonging to its school-clustering share the same RS infrastructure.

The main aspects that this architecture intends to improve, relatively to the single-instance architecture, are:

- *Performance and scalability of the global system* : The fact that there would exist multiple instances has as direct consequence in the multiplication of access points, as well as in the distribution of the total charge of the system along those different points, and so the overall system would provide a better performance and a better scalability.
- *Decentralization and autonomy.* This is one of the main advantages of this architecture, which would allow that RS's instance configuration and management would be as close as possible to the communities that most use it: the schools. Among other factors, we may work in a more productive way and answer more quickly and in a more agile way to the identified requirements. In case the central/national instance would be temporarily deactivated, the regional/local instances could be working adequately in the schools. It is important to notice that although a very significant number of functional requirements (e.g., most use-cases that are performed by teachers, students, class directors and school administrative) the accesses are performed directly on the regional/local RS's instances; other functional requirements (e.g., the parents authentication, the teacher record and historic search) will still require access to the central/national RS's instance.

On the other hand, in spite the several advantages, this architecture requires significant issues that should be adequately analysed and supported in a concrete implementation of the system. Namely (1) every instance should be installed on machines that have a permanent connection to the internet; (2) the existence of adequate technical support, preferably provided by an entity that is external to the schools; and (3) the existence of adequate management support (typically developed by the school's executive committee).

4.3 Interoperation Mechanisms

One important and complex aspect for the success of the distributed architecture is the existence of interoperation mechanisms between the central/national and the regional/local instances, in the support of the adequate distribution and information management and of some general use cases.

On the other hand, in order to support normal complementarities between RS and other information systems in the education domain, and in order to satisfy the non-functional requirement "openness and integration with other systems" (§3.2), it is relevant the public specification and exposal of a basic set of interfaces and services according to the common Internet technologies, actually designated as "web services" [6, 7].

There are some ways to describe the concept of "web service". Maybe the simplest one is the following: "a set of operations that are available at the global scale through an electronic address of the type URL". One other one, more generic, defines a web service as "an interface that describes a collection of operations that are accessible from the network through a mechanism of XML standard messages". The web services underlying technology is strongly based on the Internet, its technology and standards, such as TCP/IP, URL, XML, HTTP or SMTP. The TCP/IP, HTTP and SMTP protocols take the general role of guaranteeing the transport of messages between the web services; other protocols may also be used, such as FTP, MQ or IIOP. However, due to its ubiquity, HTTP takes the role of the *de facto* standard as a transport protocol of the exchanged messages between web services. On the other hand, to some levels, XML plays a basic role in web services, such as a mechanism of description of the data independently of the programming languages, operating systems, and computer architectures.

5 Rent@School Current state

As previously referred, RS is a project in development, being on its first iteration, in which a first prototype is being developed based on the distributed single instance architecture, but already with support for the generality of the actors and representative use-cases. For the second iteration we aim to explore the multi-instance architecture and mechanisms related to openness and interoperation.

According our plan, the first iteration takes place until September of 2002 (started in September of 2001), and the second iteration would be developed between May of 2002 and December of 2003. It is still left open the possibility of transferring the RS technology to an institutional or enterprise context that would promote and adequately support it. For more details regarding the utilization or evaluation of the RS's state the reader can consult [2, 3, 4].

6 Conclusion and Future Work

In this paper we propose and discuss the main ideas of an ambitious project that can contribute to a better future for the management of the Portuguese education system.

The RS presentation in this paper was deliberately positioned at a high level, particularly by drafting its main requirements, possible information system architectures, and integration technologies. Other documents describe the current state of the project at a detailed level, namely: the "requirements and business analysis" document [3] or the "end-users point of view" document [4].

We plan the development of this project, in research and prototype terms, along the next sixteen months and based on two iterations. The first iteration has already started and is expected to finish on September of 2002. Its main objective will be the development of a prototype application, based on the distributed and single-instance architecture, to demonstrate the original concept.

The second iteration should start next months and it is expected to finish on December of 2003. Its main interest would be the design and implementation of the RS's open and public API, as well as, the research and discussion related to organizational and information system architectures.

The Challenges of Implementing a University Copyright Policy in the Digital World

by

Donna L. Ferullo

Copyright laws are complex and can be confusing especially when trying to ascertain their applicability to digital works. Many universities have developed copyright policies to define the rights and responsibilities of their faculty, staff and students but there is a great challenge in implementing such policies. Many questions arise such as how does one reach all of the stakeholders in a university; what are the important issues for particular stakeholders such as libraries and distance learning programs; how does one educate the students about their copyright responsibilities; and how does a university navigate the legal potholes of the copyright law?

This brief paper highlights my experiences in establishing a copyright office at a major university. The University Copyright Office (UCO) at Purdue University has been in existence for two years. It was established as a result of a new copyright policy that took effect in July 2000. The policy provides some guidance about the copyright law and the expectations for faculty and staff. Students are included by referencing their honor code. The major focus of the policy is to inform the university community that they have both a legal and moral obligation to comply with the copyright law. The UCO is charged with advising faculty and staff on the use of copyrighted works for research and teaching but does not address questions of ownership of works created at the university. Educating the university community about the copyright law is also a primary responsibility of the Office.

One of the first hurdles was to develop a game plan on the best way to inform the university community that the Office existed. I met with faculty and staff from all levels and all disciplines to determine what were the questions and issues on campus and what did they think would be the best way to convey my message. It became quite apparent during the early stages that many were confused as to how copyright worked in the digital world. There was also a misconception that all educational use is fair use under the copyright law. I also discovered that many people did not even have a basic understanding of the copyright law. Even though the majority of the copyright concerns revolved around digital issues, the university community needed to have a clear, concise understanding of what the copyright law was about before they could move forward and apply the concepts to digital materials.

As I heard the concerns, I began to formulate a strategy for communicating with a diverse group of people who had very different levels of understanding. I embarked on an awareness campaign that was comprised of a combination of print, web, and targeted outreach programs.

A brochure entitled "A Guide to Copyright" was developed that condensed the fundamentals of the copyright law as it pertained to higher education. The brochure was distributed to all faculty, administrative/professional staff, and clerical staff at all of the campuses. The information in the brochure put the university community on notice that they were obligated to comply with the copyright law. As part of the educational component of the UCO, the brochure will be sent to all faculty and staff on an annual basis.

It was important for the UCO to establish a web presence on campus. The information that was included in the brochure was expanded on for the web site. Differences in the copyright law between classroom teaching and distance learning were highlighted with examples. Other components such as a Q & A section as well as a copyright news section were added. This is the second iteration of the web site and the structure and content will be changed according to the needs of the university.

The third approach was to promote the services of the Office through meetings with faculty and presentations to different groups on campus. I've worked with many of the distance learning faculty in assisting them in trying to achieve a win-win situation by using the materials they need to teach the course while still abiding by the spirit and letter of the copyright law.

Libraries also face many challenges in providing e-services and maintaining copyright compliance. There are library exemptions in the copyright law but the digital aspect for a service such as e-reserves is a bit hazy. Many times the only exemption that is applicable is fair use. Licensing access to materials is becoming more the norm for libraries than owning materials. It is therefore more important than ever for librarians to negotiate with all their vendors for the broadest possible use of materials.

The copyright issues around distance learning are certainly many and varied. The majority of concerns about copyright and distant learning revolve around what is allowed and what is not allowed for various formats of materials. Unfortunately, there is no easy answer. Many times it comes down to applying the fair use doctrine when no other copyright exemptions are appropriate.

One of the first myths that needed to be debunked is that distance learning does not necessarily mean that the professors or the students have to be in a far away place. The distance could be from one building to another on campus. Distance learning for the most part means that the professor and students are not in the same place and more often than not the learning is asynchronous.

The second myth is that everything on the Internet is free and clear to use. Many believe that no one owns the material that is posted. It is sometime difficult for many to understand that a work on the Internet enjoys the same copyright protection as a book or a journal article.

The third myth, as mentioned above, is that all educational use is fair use. Granted, fair use is probably the most utilized exemption in higher education for anything that occurs outside face-to-face teaching or classroom teaching but that does not automatically mean that every use falls within that exemption. It is critical that the university community understands the four-factor fair use test and can articulate the applicability of it to their situation. If they have made a good faith determination that their use is fair, a court can reduce the money damages if the university and/or employee are found guilty of copyright infringement.

The student honor code encompasses the rights and responsibilities for students during their tenure at the university. This certainly includes the expectation that they will comply with the copyright law. It has been my observation that students are unaware of exactly what the copyright law is and how it applies to them. Current and future students learn differently than many of their older professors. Their learning style is much more e-based than print based. To many students everything they need is on the Internet and many lack the ability to differentiate and critically evaluate the information and the source of the information such as what is provided for them through the library like full text journal databases and a web page posted by a group or an individual. If they can freely access it then it must be free. In their minds free access is equal to free use. So it is even more critical than ever for students to understand the copyright law. But how does a university make that happen? I maintain that the professors play a crucial role in educating the students not only in their discipline but also in the more fundamental requirements of the academy such as compliance with the copyright law. Educate the professor to educate the student.

In this litigious society universities must take precautions to protect themselves from both frivolous and valid law suits for copyright infringement. One of the best defenses to any such suit is to have developed and implemented a copyright policy. It is also very important that the university community be constantly aware of their responsibilities under the copyright law. A comprehensive and systematic program of copyright education and awareness will go a long way in minimizing the number of lawsuits and protecting the university.

The University Copyright Office at Purdue is still in its infancy stage but certainly great strides have been made. The number of questions that were generated by the brochure, web page and speaking engagements has risen over 500% from the first year to the second year and I fully expect that increase to continue as the Office becomes firmly entrenched in the infrastructure. I have concluded that one of the measures of success is that many people are now able to identify a potential copyright issue. They might not have the answer but they have recognized that there is an issue. The combination of that recognition and the resources of the UCO result in a win-win position for the university.

Interactive Video Content Supporting CSCL Environments

Matthias Finke

Abstract: Creating knowledge within a community on the Internet is performed with great success. Thereby, *computer supported collaborative learning* (CSCL) environments use different media formats to convey information content and to establish communication channels between participants. With this paper, we announce a design approach integrating *interactive video* content as the basic media format into a CSCL environment in order to meet the requirements for group discussion concerning knowledge creation. A system prototype has been designed with an emphasis on a navigation model for supporting the community members.

Introduction

The Internet is a global network that relies on user interactivity. The world largest hypermedia system, the World Wide Web (WWW), which is based on the Internet, was introduced in the early 90's. Due to bandwidth limitation text based information was mainly transmitted within the WWW at that time. The development of the Internet enables today's user to transmit and retrieve multimedia content like sound, images, graphics, etc. The use of the medium *video* has become quite popular on the Internet and the amount of available content is growing rapidly. Higher bit rates, which means a faster transmission of data, new compression techniques and new transfer technologies, like the streaming technology, make it possible to transmit video content on the Internet today. A rather new video format that can be found on the Internet is called *hyper video*, also denoted as *interactive video* (IAV). The general target of interactive video is to integrate the user within the presentation and to provide him with an active role that encourages him to exert influence on the way the content is presented.

We denoted interactive video as a composition of video and additional information. Additional information supports the video and can consist of different media formats, like audio, images, graphics, animation, etc. Interactive video content enables us to combine additional information with objects within a video sequence. A number of projects have focused on this subject since the beginning of the 90's as described in (Sawhney 1996 and Stotts 2002). So far, interactive video content over the WWW is determined for presentation purposes, allowing a user to view the video content and to interact with video objects in order to request additional information. This interactive presentation form has been used in e-learning environments to support the process of knowledge creation as described in (Guimarães 1999).

Creating knowledge is a process often performed by a single person, for instance, by utilizing the WWW. A different approach to creating knowledge is *collaborative learning* (CL) within communities. Within these communities, users may discuss topics or problems. Communities can have a number of different objective targets, for instance, to share experiences or to work.together on complex problems, which might be very difficult to solve by a single individual. A discussion on the WWW can be of synchronous character, like *chat-rooms* or asynchronous character, like *new groups*. CSCL can be understood as a form of knowledge creation based on group discussion that relies on both the information exchange and retrieval between distributed community members in a network.

The WWW is a basis for many communities exchanging and retrieving information content consisting of different multimedia formats to perform group discussion. So far, little has been done to provide communities with multimedia tool sets allowing them to use video content as a basis for their distributed discussion. With this paper, we announce a concept that provides a system architecture for *video based discussion forums*. The problem which will be dealt with in this paper is: *How do we support video based collaborative learning within distributed environments*?

General System Approach

The popularity and advantages of digital video content on the WWW can be associated with the *dual coding theory* as described in (Paivio 1986), which is especially true for virtual learning environments. This theory attempts to give equal weight to verbal and non-verbal processing. Furthermore, it is assumed that there are two cognitive

BEST COPY AVAILABLE

independent subsystems: one is specialized for non-verbal information and one is for verbal information. Recall or recognition is enhanced by presenting information in both non-verbal and verbal form. *This is an important aspect* for our design approach, since video content is a carrier for both verbal and non-verbal information content. Learning, on the other hand, is an active process and a high degree of interactivity is important for the success of knowledge creation. Based on the consideration of video as an audiovisual information carrier and the importance of interactivity in relation to learning processes, we chose interactive video content as a hypermedia information structure for our CSCL environment.

A video based discussion forum is based on two main components: the *presentation* and the *authoring* component. The authoring component is responsible for enabling a user to contribute to the community forum. The presentation component is responsible for presenting the information content. Information content in our design approach contains the subsets *video content*, *additional information* and *navigation data*.

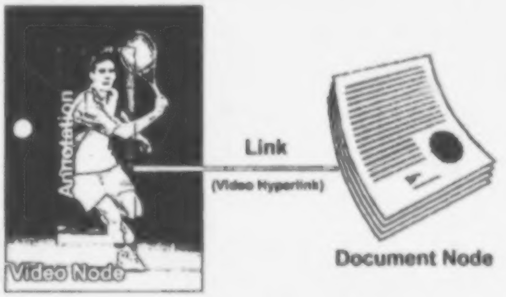

Figure 1: Video Object Linked to Document

The interactive video structure used in this system approach is based on the *Dexter Hypertext Reference Model* (Halasz & Schwartz 1994), including the notation of *links* and *nodes* that is the essence of hypertext. A *video node* can be associated with a video object like a *tennis player* in a tennis match. In contrast to a node in a hypertext document, a video node in an IAV has a spatial and temporal characteristic, since it can move within a video sequence. A video hyperlink consists of two endpoints: a video node that is associated with an object in a video sequence and a document node providing additional information about the video object. The result of the combination of video and additional information with nodes and links spans an information space, which we denote as a *video based hypermedia information structure* (VHIS). The activation of a video node leads via the video hyperlink to the presentation of the associated document node. In addition, the visualization or annotation of the video node within the video sequence supports the user with the navigation. Figure 1 shows the relation between video node, video hyperlink and document node.

An authoring component is needed when a user provides his contribution by extending the interactive video content. The authoring component can be divided into *video node authoring* and *video hyperlink authoring*. Since a video node is associated with a video object, *location data* is needed to determine the position of the video node. The generation of location data is a demanding task, see (Finke 2000). The authoring process concerning the generation of video hyperlinks is rather straightforward. The user selects a video node and defines a new video hyperlink and the document node, which is presented after activating the video node.

The video based hypermedia information structure described here can become very complex and unmanageable for the community participants. This could reduce the effect of knowledge creation within the group. Therefore, we introduce a concept to support the navigation capability of a user in such a CSCL environment. This concept visualizes the hypermedia structure, showing the user the availability of hyperlinks in a video sequence. In addition, when a member provides information for the community discussion, he has to provide additional *meta data* that specifies his contribution. The meta data set includes *user name*, *time*, *media format*, *user comment* and a *contribution category* and will also be visualized in order to support user navigation. Furthermore, this concept will support the communication within the community discussion.

System Design

A first prototype presents the *video content*, the *additional information* and provides an *authoring tool set* to extend the interactive video content with user contribution by combining video nodes with document nodes via video

hyperlinks. In addition, a discussion board is implemented in the system design, visualizing in a first approach the video hyperlink structure combined with the meta data, which describes every contribution. The discussion board helps the community members to get an overview of the ongoing discussion. Furthermore, it helps them to navigate within the interactive video structure. These functionalities are important aspects for our CSCL system design.

Figure 2: Reference Model

The system is designed as a server-client architecture enabling asynchronous group discussion for community members. Using the Internet, the system is implemented in a WWW environment using a Web browser on the client side to visualize the interactive video content and the discussion board, including a tool for providing user contribution. Figure 2 shows the main system components. On the server side, a video server streams the video content towards the client side. The information server receives the request regarding an activated video hyperlink. In addition, this server receives the meta data and the contribution of the users. The discussion server generates information for client navigation purpose based on the meta data and the dynamic interactive video structure. On the client side, there are four main components. The video engine presents the video content and is the user interface for every interaction regarding the video hyperlinks and the video controlling. The information engine represents the discussion contribution of the community members. The discussion board presents the video based hypermedia information structure in combination with the meta data. Based on the authoring engine, contributions can be provided by the community. Figure 3 shows a screen shot of the Web application. The client application front end is divided into four areas. If a user clicks with the mouse pointer on a video object, which is combined with a video hyperlink, the associated document is presented in the information window. In addition, the content of the discussion board is synchronized with the video *play-time* and will always be updated when an interaction with a video object occurs.

User Scenario

Figure 3 shows the Web application on the client side. Upon user request, the video nodes are annotated within the video stream, visualizing the video hyperlinks and thus the existence of additional information. When a user wants to activate a video hyperlink, he clicks on a video object in the *video window*. The *information window* then presents the additional information (user contribution) and the *discussion board* is updated. In the *discussion board window*, the meta data *user name*, *user comment* and *time* associated with the contribution is shown and graphically highlighted. If the user clicks on this highlighted data set entry, then the complete meta data set is presented within the *user contribution window*. This is one way to navigate through a video based discussion forum.

Another way to navigate in the video based discussion forum is by scrolling the *discussion board* entries. If a user finds an interesting entry, he clicks on it in the *discussion board window*. The *video window* then jumps to the video sequence in which the video object can be found that is associated with the entry in the *discussion board*. Furthermore, the *information window* presents the user contribution associated with that entry and the full meta data set is presented in the *user contribution window*.

As mentioned above, these two navigation options lead to the presentation of the meta data set in the *user contribution window*. In addition, the *current video node* name is also presented there. If a user wants to provide a contribution to the current video node, she chooses the NEW option and fills out the form in the *user contribution window*. The contribution along with the meta data is then sent to the server with the SEND option. A user can always delete his contribution with the DEL option. At this stage of the development, the additional information denoted as the user contribution is given in form of URL addresses.

Conclusion

We have described a video based discussion forum that takes advantage of interactive video content. Community members can exert influence over the way the interactive video based information is presented. In addition, users can insert additional information in to the interactive video structure by defining new video nodes and links into the interactive video structure. With this approach, users can exchange and share their experiences and views by inserting additional information into the presentation platform and thus into a dynamic *video based hypermedia information structure*. The integration of an advanced discussion board supports the navigation within the information structure for the community members. Since the complexity of such a hypermedia information structure can easily become quite large, a mechanism for navigation purposes is mandatory. This concept along with the integration of meta data sets is the basis for an enhanced navigation model, which provides a better understanding of the information content within a community discussion and supports the success of knowledge creation.

DISTANCE LEARNING AT SECONDARY LEVELS: CONTEXTS AND NORMS FOR THE LEARNING OF MATHEMATICS

Josep M Fortuny ,Universitat Autònoma de Barcelon, Joaquin Giménez, Universitat de Barcelona, Spain. Philippe Richard, University of Montreal , Canada

Distance Learning for Secondary Education

Since 1998 the Departaments de Didàctica de la Matemàtica i les Ciències Experimentals of both Universitat Autònoma de Barcelona & Universitat de Barcelona, develop a research project concerning the use of the Internet to attend those students who are not able to go to school regularly, specially those at the hospital or at home (Gimenez & Fortuny, 2000), and high performance athletes (Figueiras, 2000). In other papers we have discussed some aspects relating the communication model used by tutor and students under the influence of technology - web pages, e-mail, electronic forums, - and the impact that a virtual tutor has on the students participating in the experience (Figueiras, 2000; Fortuny et al. 1999). Specially in mathematics, the syntax of its language shape some of the learners' actions to make the others know about their progress.

We also detect a great influence of tutor's and students' context arising from the case studies carried out on statistics, algebra and geometry. It is an influence on both the way they manage the experience of learning at a distance, and the way they access to the contents,. This and its contribution to the norms they agree for developing the experience are the discussion points of this paper.

A great amount of the work carried out on distance training and self-learning attend university or professional levels, for it aims to be used by those adults who engage a working society highly influenced by the actual self-learning paradigm. Within this frame, it is supposed that many of the knowledge that people have when access to a job has been acquired using self-learning programs and, moreover, that it is an up to date learning (Duart, 2000; Guigou, 1999). However, this paradigm is quite different when adapting and justifying the use of new technologies for communication in secondary levels of education, for aspects such as affect, curricular constraints, and the influence of technology on the motivation and willingness to learn, become more valued (Brieba, 2000): Personal contact among peers and teachers has a high relevance at this level of education and responses to questions concerning why should we introduce distance learning experiences has not an immediate answer. Standards for secondary education emphasise objectives to be carried out in a classroom setting, such as peer-discussion in a community; handling of objects in the space; learning how to speak and moderate a debate; and we are far away from consolidated proposals joining the use of distance learning to the objectives of the actual curricula. Rejecting simplistic approximations concluding if the conversion from a non-technology-oriented course structure to a technology-oriented one led to a quantifiable difference of any sort, our commitment in this specific project is a social and politic one: distance education at a secondary level to attend those people for whom it seems to be the best opportunity, specially the use of the Internet.

Dynamic contract, sociomathematical norms and context influences

Different situations led us to adapt learning units for learning at a distance to the different contexts in which the learners develop their activity. Evidence in the cases studied suggests focus in the way it modifies the design of the learning environments and curricula adaptation for each setting.

The influence of the family is an important factor to take into account with hospitalised students (Muria et al. 2000). When students work at home, and even when they communicate with their tutors, usually do it in the company of their relatives, who work with them. If the correspondent activities do not take into account this factor, there is no possibility for the tutor to follow the student by observing only their communication via e-mail, and there is a need to engage the family in the experience and make explicit their role together with the ones of tutors and students. This is the main point to create a new setting for learning and not to force the students to reproduce at a distance the norms and constraints which they have learnt that prevail in the classroom.

This must be also applied to the case of high performance athletes, who due to sport training must be absent from school for long periods of time. However, the role of the family has almost no influence when planning or designing the environment to be used during the tutorial, but the hard training sessions and press of the competition arise as the main factors that mould the learning experience of the student:

> *I am a bit lost with these of determinants. I did not know how to do anything for you and I hope that you will help me tomorrow. The videoconference doesn't work, it may be the change of the modem, I don't know. Let's meet tomorrow at 12h o'clock to communicate by telephone or chat. Maybe that the championships are coming closer and I cannot concentrate.* (Figueiras, 1999)

This kind of assertions are a key to adapt the contents to the special situation of the student, and shows not only the influence of the natural context in the student's activity, but the implicit agreements arising during the experience. It is important for the tutor to recognise it as a new agreement in the relationship that he/she construct with the student. In the example above, the student assumes that the high grade of flexible learning permits him to look for spaces of collaboration in order to cover the program. This occurs not at the beginning of the tutorial but later, while he maintains a personal relationship with his tutor.

Therefore, we face different norms or rules, what we here roughly label as *contract*, some of them implicitly assumed by the learners as a result of their interaction, and some of them stated from the very beginning of the experience (fig. 1). Moreover, these rules are continuously re-negotiated, and new ones appear leading us to a dynamic view of this contract. It is not possible to conduct the experience under the rules of a planned contract unless it deal with this dynamic process. Keys for the construction of these rules need to be recognised by the learners and, in the contexts of distance education we are dealing with, they must look for them in their written conversations via e-mail. For this reason is important to describe and familiarise with the kind of actions that permit us to communicate and collaborate at a distance. If the participants learn how to participate (by writing) on a electronic conversation and how to express ideas related to the specific contents, they mould their actions to make the other know about their own interests, implicitly or explicitly. Distance learning and people who engage on-line courses require a new interpretation of *context* and its dimensions (Badia et al. 2000).

Two main aspects are directly related with the context of the experiences we are discussing: the design of the activities concerning didactical and pedagogical issues of the course proposed, and an important and not yet sufficiently investigated question: the student's rejoining the school setting after the conducted tutorial.

Adapted Design for a dynamic process

For each one of the cases proposed to be attended, a web based environment is prepared for the student to cover the same curriculum which is considered at the corespondent school. Thus, there is a decision to give priority to the program followed by the current teacher. To this extent, the main point in the exploratory studies has been to investigate the way in which this new learning settings permit the student to follow his or her learning activities, more than to innovate or to experiment a new *mosaic* knowledge, as a hypertext system like the Internet suggest.

Interactive points have been used, discussed and analysed to know and let the learners know about socialisation roles of tutor and students, and its influence in the relationship among them and the materials. Internet is the most significant contact with the mathematical activity for these students, and giving references, using reactions, or emotional activation resources, are considered beyond a classical *talk-with-the-tutor* way of interaction. Figure 2 enlighten this points attending a personal experience of a sick student studying at home.

Design of the tutorial units and adapted curriculum

We have analysed some crucial aspects of a unified model of conducted-at a distance tutorial concerning several experiences with secondary students. It is important to emphasise the differences between this kind of precise support for some students, and general courses designed totally to be carried out at a distance, specially what concerns to design, evaluation and implement *(Muria et al 2000). In the sections above, starting from some researches on the* cases conducted in the project we offered the main points to be taken into account in the planning phase: contact with the family when appropriate; sharing from the beginning the initial rules and objectives to take into account; and flexible -collaborative, personal- design of the virtual learning environment.

But attending the end of the experience, it is more important to ensure the students' rejoining the school setting and the adaptation to the way of assessment of his or her current teacher at the school than evaluate the goals or benefits of the distance environment alone. We have detected that new habits of reading and writing, offering of open responses due to the asynchronicity of the distance conversations; and creativity arising from the contact with a virtual environment contribute to shape the learners' experience after the tutorials. Concerning the cases we are discussing here, this led us in the future to evaluate which of the interactive issues arising in the experience of learning at a distance are used by the students once they came back to their classroom setting.

This project is supported by the DGICYT, reference PB96-1201 and a grant from the Comissionat per a Universitats i Recerca de la Generalitat de Catalunya.

Abstract:

We analysed some crucial aspects of a unified model for conducting distance tutorial concerning several experiences with secondary students. It is important to emphasize the differences between this kind of precise support for some students, and general courses designed totally to be carried out at distance, specially in relation to design, evaluation and implementation. At attending the end of the experience, it is more important to ensure the students' insertion in the school setting and the adaptation to the way of assessment of his or her current teacher at the school than evaluate the goals or benefits of the distance environment alone. We have detected habits for reading and writing, offered open responses due to the asynchronicity of distance conversations; and creativity arising from the contact with a virtual environment contribute to shape learners' experience after the tutorials.

DISTANCE LEARNING FOR SECONDARY EDUCATION

Since 1998 the *Departaments de Didàctica de la Matemàtica i les Ciències Experimentals* of both *Universitat Autònoma de Barcelona* and *Universitat de Barcelona*, develop a research project concerning use of the Internet for students who are not able to go to school regularly, specially those at hospital or at home (Gimenez & Fortuny, 2000), and high performance athletes (Figueiras, 2000). In other papers we have discussed some aspects relating the communication model used by tutor and students under the influence of technology -- web pages, e-mail, electronic forums, -- and the impact of a virtual tutor has on students participating in the experience (Figueiras, 2000; Fortuny et al. 1999). Especially in mathematics, the syntax of its language shape some of the learners' actions to make the others know about their progress.

We also detected a great influence of tutor's and students' context arising from the case studies carried out in statistics, algebra and geometry. It influenced both the way they managed the experience of learning at a distance, and the way they accessed the contents. This and its contribution to the norms they agreed for developing the experience were the discussion points of this paper.

A great amount of research on distance training and self-learning has been conducted at university or professional levels, for it aims to be used by those adults who engage a working society highly influenced by the actual self-learning paradigm. Within this frame, it is supposed that most of the knowledge that people have while accessing to a job has been acquired using self-learning programs and, moreover, that it is an up-to-dated learning (Duart, 2000; Guigou, 1999). However, this paradigm is quite different when adapting and justifying the use of new technologies for communication at secondary levels of education, for aspects such as affect, curricular constraints, and influence of technology on the motivation and willingness to learn, become more valued (Brieba, 2000). Personal contacts among peers and teachers has a high relevance at this level of education and responses to questions concerning why should we introduce distance learning experiences has not an immediate answer.

DYNAMIC CONTRACT, SOCIOMATHEMATICAL NORMS AND CONTEXT INFLUENCES

Different situations led us to adapt learning units for teaching at a distance to the different contexts in which the learners develop their activity. Evidence in the cases studied suggested focus in the way it modifies the design of the learning environments and curricula adaptation for each setting.

The influence of the family is an important factor to take into account with hospitalized students (Muria et al. 2000). When students work at home, and even when they communicate with their tutors, usually they do so in the company of their relatives, who work with them. If the correspondent activities do not take into account this factor, there is no possibility for the tutor to follow the student by observing only their communication via e-mail, and there is a need to engage the family in the experience and make explicit their role together with the ones of tutors and students. This is the main point to create a new setting for learning and not to force the students to reproduce at distance the norms and constraints which they learnt that prevail in the classroom.

This must be also applied to the case of high performance athletes, who due to sport training must be absent from school for long periods of time. However, the role of the family has almost no influence when planning or designing the environment to be used during the tutorial, but the hard training sessions and pressure of the competition arise as the main factors that mould the learning experience of the student:

> I am a bit lost with these of determinants. I did not know how to do anything for you and I hope that you will help me tomorrow. The videoconference doesn't work, it may be the change of the modem, I don't know. Let's meet tomorrow at 12h o'clock to communicate by telephone or chat. Maybe that the championships are coming closer and I cannot concentrate. (Figueiras, 1999)

This kind of assertions is a key to adapt the contents to the special situation of the student, and shows not only the influence of the natural context in the student's activity, but the implicit agreements arising during the experience. It is important for the tutor to recognise it as a new agreement in the relationship that he-she is constructing with the student. In the example above, the student assumes that the high grade of flexible learning permits him to look for spaces of collaboration in order to go through the whole program. This occurs not at the beginning of the tutorial but later, while he maintains a personal relationship with his tutor.

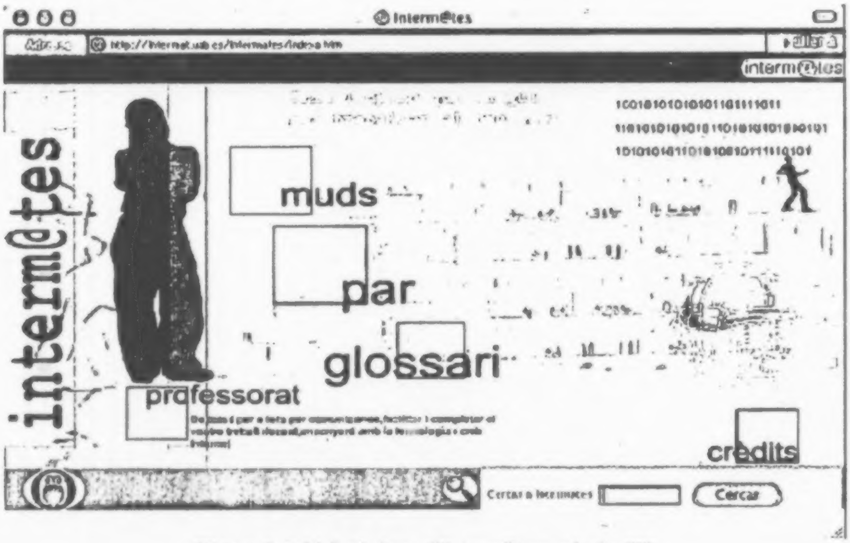

Figure 1: Initial window of Interm@tes web-site [1]

Therefore, we face different norms or rules, what we here roughly label as *contract*, some of them implicitly assumed by the learners as a result of their interaction, and some of them stated from the very beginning of the experience (fig. 1). Moreover, these rules are continuously re-negotiated, and new ones appear leading us to a dynamic view of this contract. It is not possible to conduct the experience under the rules of a planned contract unless it deals with this dynamic process. Keys for the construction of these rules need to be recognized by the learners and, in the contexts of distance education we are dealing with, they must look for them in their written

BEST COPY AVAILABLE

conversations via e-mail. For this reason it is important to describe and familiarize with the kind of actions that permit us to communicate and collaborate at a distance. If the participants learn how to participate (by writing) on an electronic conversation and how to express ideas related to a specific contents, they mould their actions to make the other know about their own interests, implicitly or explicitly. Distance learning and people who engage on-line courses require new interpretation of *context* and its dimensions (Badia et al. 2000).

Two main aspects are directly related with the context of the experiences we are discussing: the design of the activities concerning didactical and pedagogical issues of the course proposed, and an important and not yet sufficiently investigated question: the student's return to the school setting after the conducted tutorial.

ADAPTED DESIGN FOR A DYNAMIC PROCESS

For each one of the cases proposed to be attended, a web-based environment was prepared for the student to cover the same curriculum, which is considered at the correspondent school. Thus, there is a decision to give priority to the program followed by the current teacher. To this extent, the main point in the exploratory studies was to investigate the way in which this new learning setting permits the student to follow his or her learning activities, more than to innovate or to experiment a new *mosaic* knowledge, as a hypertext system like the Internet suggests.

Interactive points have been used, discussed and analysed to know and let the learners know about socialisation roles of tutor and students, and its influence in the relationship among them and the materials. Internet is the most significant contact with the mathematical activity for these students, and giving references, using reactions, or emotional activation resources, are considered beyond a classical *talk-with-the-tutor* way of interaction. Figure 2 enlightens this point attending a personal experience of a sick student studying at home.

DESIGN OF THE TUTORIAL UNITS AND ADAPTED CURRICULUM

Mainly, the web-based environment was built in a hypertextual form starting from the disciplinary contents and technological aspects. The disciplinary contents were structured according to a catalogue of key questions which cover of compulsory secondary education, age 12 to 16, adapting at the beginning the modular base and the pedagogical principles of *Bon dia Mates* project – curricular material which was financed, diffused and published in paper version by the *Departament d'Ensenyament* of *Generalitat de Catalunya*, of which a static web version by the *Programa d'Informàtica Educativa*. However, the access to the contents, which vary with the needs of the users, is possible not only starting from a glossary, blocks of matters, a set of questions-answers game and an internal search engine, but also starting from mini didactic units (fig. 3). The latter were organized

BEST COPY AVAILABLE

to launch a progressive study of the key questions with various points of interactivity, including elements of orientation, regulation and synthesis for the pupil and the teacher, in addition to the possibility of communication with the peers or the tutor. In the case of complex key questions, as on figure 3, we developed the organization of the tutorial units thanks to behavioural research (Richard, 2002).

Privacy and Anonymity in an Online Course: Perceptions and Expectations of Distance Education Students

Dannie B. Francis, Department of Adult Learning and Instructional Technology, University of Wyoming, United States, DannieFrancis@email.msn.com

Guy M. Westhoff, Department of Adult Learning and Instructional Technology, University of Wyoming, United States, westhoff@uwyo.edu

Abstract With the emergence of the Internet and the increased use of online courses, email, and chat rooms, the issues of privacy, anonymity and the security of personal information have evolved to a new level of importance. These issues have been discussed extensively as related to open access of online services, but have only lightly been addressed with regard to students in online courses. Online distance education courses bring into play a new set of classroom variables and factors, particularly the attitudes and expectations of distance education students who are making use of the Internet to further their education. This study sought to answer the question: What are the perceptions and expectations of students in an online course with regard to privacy and anonymity? Results indicated that the respondents shared a noncommittal attitude toward privacy and anonymity issues expressed a lack of concern for the issues.

Introduction

"The fundamental concept of distance education is simple enough: teachers and students are separated by distance and sometimes by time" (Moore & Kearsley, 1996, p. 1). Correspondence and independent study courses were the first generation of distance education classes. "The earliest documented home study course offered in the United States was shorthand" (Moore & Kearsley, 1996, p. 20). The State University of Iowa began radio broadcast courses for credit in February of 1925 and followed up in 1934 with courses in oral hygiene and identifying constellations through television broadcasts (Moore & Kearsley, 1996, p. 27). This ushered in the broadcasting and teleconferencing era of distance education. The Open University was introduced as a key player in distance education in the 1960's and 1970's. In 1991 the World Wide Web introduced us to the third generation of distance education classes. "By June 15, 1995 seventy three percent of the countries of the world were Internet connected to some degree" (Khan, 1997, p. 20) and online classes were ready to be launched into homes all across America.

The relatively recent phenomenon of online education has opened the door to many research opportunities. Among the research options have been several studies conducted concerning privacy and anonymity of persons who use the Internet (Bodi, 1998; Descy, 1997; Metivier-Carreiro & LaFollette, 1997; Singleton, 1998). While privacy issues are not unique to the Internet, Holt (1998) reminds us that "risks may be magnified by the power and reach of electronic systems," and to date studies have not addressed students of online classes. This study will specifically address such students and ask the question, "What are the perceptions and expectations of online students with regard to privacy and anonymity?"

Privacy is defined as all information available in an online class, which can be used to identify the student taking the class. Examples of privacy information for students include name, address, phone number, age, gender and social security number. Anonymity is defined as the ability to take a class without other individuals being aware of your identity or personality. An example of this would be allowing students to use an alias for class instead of their real name.

The face-to-face interaction of the traditional classroom usually results in students revealing some components of their personality. Race, gender and age are examples of traits that are immediately open to the scrutiny of other students while grooming habits, shyness or a tendency to be outspoken are traits that might reveal themselves over a period of time. Distance education, and more specifically, online courses bring into play a new set of classroom variables and factors (Holt, Kleiber, Swenson, Reess & Milton, 1998). Students who are typically reserved in a traditional classroom might "blossom" in an online class and with greater participation by a larger number of students, the usually dominant personality might become just another voice in the class.

Because there are environmental differences between traditional classrooms and online courses this study will explore what expectations and perceptions exist with regard to privacy and anonymity in online courses. Other studies have shown that individuals who utilize Web-based commerce such as email and chat rooms do expect some level of security with regard to their privacy, and educators should be aware of this concern for their online students (Holt, 1998).

In a study conducted at the University of Wyoming (Novick & Francis, 2001) a class of twenty-nine students were surveyed for their opinions on privacy and anonymity within their online courses. Of the twenty-nine students surveyed slightly over forty-one percent responded. Of the students who responded, those who had taken two or more online courses showed less concern over privacy and anonymity issues than those who were new to online education. The strongest reactions were to the question, "Should a student be able to use a pseudonym for chats and threaded discussions?" A little over eighty-three percent of the respondents disagreed or disagreed strongly with this concept. Mild concern was expressed over the sharing of home phone numbers and addresses while video streaming for chats and biographies were basically neutral showing no concern against or enthusiasm for the concepts. A copy of this study is available in the 2001 National Meeting proceedings from AECT.

Methods

Students in outreach programs offered by the University of Wyoming were offered the opportunity to complete an online survey regarding attitudes towards issues of privacy, anonymity and personal information sharing in an online educational environment. The survey was offered in April and May of 2002. The survey instrument was built in Macromedia's Dreamweaver 4 software using radio buttons and text boxes as the response method. The URL for accessing the survey was sent to students by email with the assistance of the University of Wyoming Outreach School. Students who chose to participate were asked to select the provided URL and complete a questionnaire consisting of a demographics section and twenty attitude questions. The attitudes questions were rated on a Likert scale with five categories ranging from strongly agree to strongly disagree.

The responses were submitted via the Internet directly to the researcher when the respondent chose a submit button at the end of the survey. Likert responses were weighted one through five. The responses were tallied with a strong concern for privacy or anonymity resulting in a high score (5) while a strong preference for openness or minimal privacy and anonymity resulted in a low score (1). Of the twenty questions ten were related to issues of privacy and ten were related to anonymity. Statistics were performed using SPSS.

Findings and Conclusions

This study showed that online distance education students had similar attitudes towards issues of privacy and anonymity within the online course. These attitudes were noncommittal and expressed a lack of concern or previous thought about the issues of privacy and anonymity. Moss (2000) identified that users of chat rooms and e-commerce expect a certain level of security. However, from the results of this study it appears that students in an online distance education course do not. This result could be attributed to the fact that these online students are interacting within an environment where access is controlled via password protection.

The increase in web-based distance education courses and entire degree programs offered online, it is important to determine student attitudes toward the issues of privacy, anonymity, and sharing personal information and the degree these attitudes impact the success of the course and students in online courses. Future studies need to be conducted to ascertain specific attitudes related to the issues of privacy, anonymity, and the sharing of personal information by the students in an online distance education course.

Blended Learning: What is it? How does it impact student retention and performance?

Patricia C. Franks

Many institutions have developed educational programs that provide a continuum of totally on-campus courses, supplementary Web-enhanced courses, and completely online courses (Pittinsky, 2001).

Since the early days of universities, a traditional oral lecture has been a keystone of higher education (Brusilovsky, 2000). Even distance learning is not new. Major universities including The University of Michigan and Ball State University in Indiana literally created distance learning 15 years ago as a revenue producer. Rio Salado College, one of ten colleges in the Maricopa County Community College District of Phoenix, Arizona, has provided distance learning for more than twenty years (Walczak, 1999).

Educators who have tried both approaches realize that neither the traditional lecture format nor the distance education approach is appropriate for every student, every teacher, and every course. This leads us to a third option, blended learning.

Blended Learning

A blended approach to learning is accomplished by leveraging technology to make education more accessible. "Simply put, blended learning is learning that employs multiple strategies, methods, and delivery systems ("The Node Learning", 2001)." Blended learning is sometimes referred to as "integrated learning," "hybrid learning," or "multi-method learning." The primary focus of this article is on the integration of classroom- and Internet-based resources in ways that improve conditions for teaching and learning.

To create a successful blended learning approach to teaching and learning, two tools are essential: 1) learning technology and 2) blended learning strategy (McArthur, 2001).

Learning technology enables the instructor to create course materials in different formats including printed textbooks, online textbooks, online lecture notes, QuickTime movies, CDRoms, PowerPoint Presentations, streaming media, and videotapes of lectures and demonstrations. Dr. David Rose, co-director of the Center for Applied Special Technology (CAST), believes in providing students with "multiple representations of information" and a menu of different ways to get the information they need (O'Neill, 2001).

A blended learning strategy must be developed to identify the best "blend" of strategies, methods, and medias to help students meet the course objectives.

Blended Learning as a Process

It's important to understand that instructors don't create successful blended courses in one fell swoop ("The Node Learning", 2001). The best approach is to use your course goals plus identified teaching and learning objectives as a basis for your blended course. Remember, teaching and learning come first, technology follows. Stephen Ehrmann ("The Node Learning", 2001) puts it another way: "If you're headed in the wrong direction, technology won't help you get to the right place."

Once you clarify your goals and objectives, you're ready to determine the best method to achieve them. Technology can help in one of two ways: 1) by providing administrative or logistical support for the instructor and students and 2) by enhancing teaching and learning.

If you want to develop your blended course in stages, it may progress something like this:

1. First, provide administrative and logistical support for your students and yourself by posting your current syllabus, office hours, and a list of course references on line.

2. Then add a discussion forum or chat room for students to ask questions or discuss assignments outside of class.
3. Next, post course materials such as lectures, course notes, and presentation slides online.
4. Finally, revise the entire course to take advantage of some ways in which the web can help create a more active learning environment. For example, for a class that meets for 1 hour and 15 minutes twice a week, deliver live lectures and demonstrations in a large lecture hall one day. Instead of meeting in person the second day, facilitate online group work.

Embrace blended learning if you believe it will enhance teaching and learning in your courses. But don't be disappointed if things don't work out the way you planned the first time you try this approach. Remember, blended learning is a process, and evaluation is an important part of the process. You may need to rethink the ways in which you evaluate student performance. For example, if you assign online discussion questions, you will need to determine criterion on which to base a grade for discussion responses.

Blended Learning at BCC

Until the Fall of 2001, instructors at BCC had only two options: 1) to teach in a traditional fashion without an online component for their students or 2) to teach an entire course online. There was no middle ground. Only students enrolled in distance learning courses through the SUNY Learning Network had the opportunity to interact with others in a flexible but challenging asynchronous environment. All of that changed when WebCT, an online course development and management system, was implemented. It was used to provide an online component for six courses in the Fall of 2001. By the Spring of 2002, the number of WebCT supplemented courses grew to 23.

As stated earlier, the primary focus of this article is to discuss the integration of classroom- and Internet-based resources in ways that improve conditions for teaching and learning. Instructors interested in using WebCT first considered the goals and objectives identified for their own courses and their students. Then they decided how an online supplement using WebCT could help them achieve those goals and objectives. Some decided to post course materials and engage in discussions with students. Others posted lectures and PowerPoint Presentations. Still others created online tests and quizzes.

Traditional classroom instructors weren't the only ones to recognize the benefits of using WebCT to enhance their courses. Three instructors teaching either in our synchronous distance learning room (Luminet) or teaching video-based courses decided to use a WebCT supplement to engage students in discussions, and the instructors of four SLN courses opted to supplement those courses with WebCT in order to utilize the testing component.

Comparison of Student Success Rates Determined By Completion of an Introductory HTML Course and Average Class Grades Earned

The introduction of WebCT at BCC provided many instructors with the option to incorporate web-based technology into their on campus courses. In some cases, sections of those courses had already been taught completely online through the SUNY Learning Network. For the first time, statistics could be compiled to compare the retention rate of students in blended courses with sections of the same course taught in the traditional mode and completely online. One such course is BIT 173 – Basics of Web Page Creation.

Data was gathered from two online sections of BIT 173 taught completely over the SUNY Learning System, two sections of BIT 173 taught completely on campus without the benefit of an online supplement created in WebCT, and two sections taught on campus with an online supplement. Since students taking online courses are not required to take placement tests, it is not possible to compare entry-level skills or knowledge of the students enrolled in any of the sections. Therefore, only retention rates and final grades were used in this comparison. Consistency was provided across all sections and semesters by providing students with the same syllabus; assigning the same readings, activities, and discussions; and requiring students to take the same examinations and complete the same midterm and final projects. The same

BEST COPY AVAILABLE

instructor taught each of the sections included in the study. The main difference was in the delivery method used. The figures are summarized in the table below.

Comparison of Success Rates of Students Enrolled in Different Sections of Basics of Web Page Creation Based on Delivery Method

Retention Rates and Average Grades

Delivery Method	Semester	Number of Students Completing Course	Retention Rate	Average Grade
Traditional – on campus with no web-based material	Spring 2001	49	83% (96% after students who earned a GPA of 0 were excluded)	2.67
Blended - on campus supplemented with WebCT	Fall 2001	50	79% (90.9% after students who earned a GPA of 0 were excluded)	2.896
Completely online through the SUNY Learning Network	Spring 2001 and Fall 2001	30	75% (85.6% after students who earned a GPA of 0 were excluded)	3.346

Limitations

The figures above do take into account some variables, such as the removal of one student who audited the course since no numeric grade was available. Students who earned a GPA of "0" were excluded from the computations since they completely dropped out of school. Their failure to complete may have had more to do with personal problems or second thoughts about school in general than completion of this one course. Of course, a separate study looking at retention within the college system would want to include those students.

Entrance exam scores were not available for online students and students not enrolled in a degree program, and no pre-test was given to students. Therefore, it is not possible to know if the students entered with comparable skills and knowledge.

More detailed information related to the statistics reported above will be available at the conference.

Findings

The table above highlights two outcomes in which this research was interested, retention rate within the course and average class GPA based on the method of course delivery. The traditional courses included in the study were 3 sections of BIT 173 – Basics of Web Page Creation – 2 day sections and 1 evening section. The blended courses were taught in the Fall of 2001 and included 4 sections of the same course – 3 day sections and 1 evening section. Although the retention rate and success rate as evidenced by average GPA was better for the blended course than the traditional, it is not possible to know if the fact that class sizes were slightly smaller had any impact. The completely online courses experienced the lowest retention rate but the highest GPA. One section taught in the Spring of 2001 and one taught in the Fall of 2001 were used in this study. No other sections of these courses were taught on campus in the Fall or Spring 2001 semesters.

BEST COPY AVAILABLE

In the case of the Internet-only courses, the instructor had been familiar with the software and hardware, having taught at least one online course each semester for the previous four years. In the case of the courses supplemented by WebCT, the technology was new and the semester used in this study being used on campus for the first time. It was as new to the instructor as to the students. It would be useful to compare the retention rates and average GPA by method of delivery in a second semester to this first semester to see if the instructor's familiarity with the technology has any bearing on student retention and achievement. The same instructor is again teaching 3 blended courses and 1 completely online course this semester, which ends the middle of May. The report will be updated to reflect these figures and presented at the conference.

Closing Thoughts

In the very near future, greater bandwidth, faster processing speeds, and better software will enable students to download larger files more quickly. Instructors will be able to create even more interactive and entertaining web courses. Multimedia may actually be viewed as just another teaching tool. And wireless devices will facilitate access to courses anytime and from anywhere.

In the past few years, much emphasis has been placed on the technology. Professors employing the new technology to post course materials are becoming more efficient. Now it's time to concentrate on pedagogical issues related to the use of technology to see if we can help instructors become more effective.

Those individuals who thought distance education would replace traditional classes were wrong. But so were the individuals who predicted that distance education was a passing fad. Both are here to stay – and blended learning is an exciting alternative to both.

The Effect of Interactive Applets in Mathematics Teaching

George Gadanidis
Faculty of Education
University of Western Ontario
Canada
ggadanid@uwo.ca

Abstract: Interactive applets, which are typically web-based, are the most recent manifestation of technological tools used in mathematics education. This paper briefly reports on recent case studies of three grades 5-6 and one grade 10 teacher where the use of web-based applets may have acted as pedagogical models for teachers' classroom practice, shifting the teaching focus from the learning of isolated concepts to algebraic relationships among concepts. The paper also describes an upcoming study of the affect of the availability of interactive applets on the pedagogical thinking of teachers.

Interactive applets, which are typically web-based, are the most recent manifestation of technological tools used in mathematics education. They are unique in their focus on small interactive units, due in large part to the current nature of web-access where large programs are unwieldy and quickly exhaust download capabilities and user patience. Well designed interactive applets enable students to engage in investigations of mathematical relationships without having to spend a lot of time learning how to use the tool that creates the various representations of these relationships. For example, the Maximize Area applet (ExploreLearning, 2000a), shown in Figure 1, enables students to investigate multiple representations of area and perimeter relationships. The focused and user-friendly nature of well-designed interactive applets may make them appropriate as models of mathematical concepts and of new pedagogical directions, as is the case at the Illuminations.nctm.org web site of NCTM (2001).

Some research indicates that "our thinking is deeply molded by material devices and socio-technical collectives" (Levy, 1993, p. 10). Perhaps well designed and easily accessible interactive applets that allow students and teachers to use and explore mathematical relationships may affect what Levy refers to as the "cognitive ecology" of learning environments (Levy, 1993). It may be possible that "new forms of representation change the mathematics being taught" (Confrey, 1993, p. 335). New media not only enable us to express our ideas in new ways – they also affect the ideas we have. "We don't always have ideas and then express them in the medium. We have ideas *with* the medium. Making progress is an episode of materially mediated thinking – reasoning or coming up with a new idea – happens jointly in the mind and in the medium at every stage" (DiSessa, 2000, p. 116). And perhaps more importantly, some research indicates that there may be a spillover effect, where learning to think with material devices affects our thinking even when the devices are not present (Borba & Villarreal, 1998). However, some research also indicates that attempts to change teachers' mathematics conceptions and teaching practice "are minimally effective, in part because teachers filter what they learn through their existing beliefs" (Stipek et al 2001, 214) and teachers assimilate new ideas without substantially altering existing beliefs that drive their practice (Cohen & Ball 1990).

This paper briefly reports on recent case studies of three grades 56 and one grade 10 teacher using web-based interactive applets in their teaching of mathematics. The paper also describes an upcoming study of the affect of the availability of interactive applets on the pedagogical thinking of teachers. In the cases described below, teachers were first introduced to a variety of web-based interactive applets. The teachers selected which applets to use in their teaching based on the mathematics topics in their next unit of study. The three grades 5-6 teachers chose an applet dealing with measurement (Figure 1) while the grade 10 teacher chose an applet dealing with the vertex form of a quadratic function. (Figure 2) (ExploreLearning 2000a; 2000b).

Brief summary of the use and effect of interactive applets

The Maximize Area applet (Figure 1) may have acted as a pedagogical model for grades 5-6 teachers' classroom practice as the approach to teaching about area and perimeter described above varies from the norm. In previous years, teachers in the study did not focus on the relationships between area and perimeter. Their typical approach to area and perimeter is more reliant on the development and use of formulas, with minimal emphasis on the relationship between area and perimeter. The grade 5 teacher said, "I think I do more the traditional way, separating the two." One of the grade 6 teachers said, "I do perimeter first." The grade 5 teacher reflected on the effect of this difference on students: "When I introduced area and perimeter [in previous years] they didn't see a relationship between the two, but when you fix one at a given constant, and you can manipulate the other, they really found that pretty neat."

The grades 5-6 teachers used the Maximize Area applet in the context of teaching a unit on measurement. They met and decided on the general direction for the classroom and online activities. The grade 5 teacher then used their ideas to develop a detailed lesson that was shared with the grade 6 teachers. The lesson plan started with the following problem: "We're going to build a pen for your dog. Your parents are going to go out and buy 24 metres of fence. You're going to build it with four sides. How are you going to get the biggest area for your dog to play?" In the grade 5 classroom, the teacher drew one possible pen configuration on the board and then asked the students to find and draw all possible configurations on grid paper. Then students developed a table of values, recording the dimensions of the pens they had drawn, and they plotted area versus length on a graph. Students had previous experiences plotting straight line graphs and were surprised that the area graph was curved. "And they said oh that's kind of a neat shape because they're used to […] getting a straight line […] and the reason I wanted to do that [in class] was because once they go to the computer that is what they are going to see. […] I didn't want them to go to the computer right away because […] I think they would see the graphs and say that's neat but not relate it to any meaning […] I think that was a big key for their understanding." The next day, the grade 5 students went to the computer lab and were asked to solve the problem where the perimeter is 20 metres. The teacher was impressed with how well students understood and solved the problem of finding the pen with maximum area. "They liked seeing this, they liked seeing the area changing." The teacher was also surprised "because I have some grade fives that are not top grade fives but all of them got it." Some students asked, "is the biggest area always a square? […] Wouldn't a circle be bigger? […] They were really thinking."

In contrast, the grade 6 teachers decided to do the computer lab component of the lesson before they did the classroom component. They did this because of minimal access to the computer lab and because of the tight timelines of other classroom activities. In the computer lab, the grade 6 teachers noticed that some students were not focusing on the problem at hand when they were using the Maximize Area activity. "Some of them thought it was a toy […] changing sliders all over the place." The grade 6 teachers stated that they felt students going to the computer lab were expecting something different, "it seems they were expecting a game or a fun activity." They noted that the activity worked better with the grade 5 students because "your kids knew what to expect when they went to the lab because they had done those kind of activities (in the classroom), and they knew what the problem was all about." The grade 6 teachers said that next time they would reverse the order of the lesson activities, to match the sequence used by the grade 5 teacher.

In the case of the grade 10 teacher, the effect of using the Quadratics: Vertex Form applet (Figure 2) appears to have shifted the pedagogical focus from studying the individual and isolated effects of coefficients of quadratic equations to a holistic and dynamic exploration of relationships between quadratic equations and graphs. The teacher used the applet in a lab setting where each student worked on their own computer. Students however collaborated in some cases to discuss

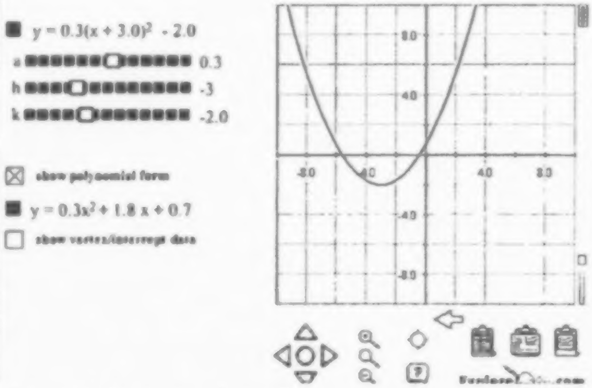

Figure 2. Quadratics: Vertex Form applet.

what they discovered and to check their answers and understanding. Students were provided with a set of worksheets prepared by the teacher. The worksheets included: (1) An explanation of how to log in to the school network and how to access the applet online; (2) a set of guided investigations, questions and instructions; and (3) a self-test section where students manually graphed quadratic functions in vertex form and used the applet to check their answers. As students worked through the worksheets, the teacher was surprised at how focused the students were and how well they seemed to understand. However, he indicated that he would withhold judgement until he saw how well students would do on an upcoming unit test. The teacher used the same unit test that he had used in a previous semester with a different class and compared the results of the two classes. The test scores on the topic of the vertex form of a quadratic of his current students were significantly higher than the test results of students in the previous semester who used graphing calculators (approximately a 30% difference in test scores on average). Although student ability can vary from class to class, the teacher felt that the two classes were generally of similar ability and that the test score difference was significant.

In previous semesters, the teacher taught the vertex form of a parabola using graphing calculators where over a sequence of three different classroom periods, students explored the effect of coefficients a, h and k, respectively, using the graphing calculator and then moving to paper and pencil graphs. A fourth classroom period was used to consider the effect of all coefficients simultaneously. When using the Quadratics: Vertex Form applet, the teacher spent only two classroom periods on the topic: one in the lab (as described above) and one in the classroom to reinforce concepts using paper and pencil activities and graphs. The teacher noted that his approach changed when using the Quadratics: Vertex Form applet in that he started with the big picture first (exploration of relationships between all there coefficients and the graph) rather than considering each coefficient in isolation. He also noted that he spent much less time teaching this topic (about half the time). The teacher felt that in contrast to the Quadratics: Vertex Form applet, his previous use of graphing calculators did not allow students to see the dynamic nature of relationships between coefficients and graphs and that the graphing calculator user interface is relatively primitive.

Both studies involved the use of a single web-based applet on a limited basis. The studies offer some support for existing research that shows that material resources affect the mathematics taught (Levy, 1993; Confrey, 1996; diSessa, 2000) by shifting to some degree the mathematics teaching focus from isolated concepts to relationships among concepts. However, the specific effects in each of the classrooms, including the level of pedagogical success experienced by the teachers, varied. More research is needed to explore the potential use of interactive applets as models of mathematics relationships and teaching practice.

Upcoming research

In 2002-2003 a follow-up study will be conducted to investigate the nature of the pedagogical thinking, and more specifically the lesson planning, of mathematics teachers when designing lessons on given topics, with and without access to interactive applets similar to those shown in Figure 2 and Figure 3 (MathAdventures.com 2002). Does the availability of interactive applets whose focus is on exploring mathematical relationships affect the lessons designed by teachers? The study will involve 16 teachers and will have four stages. Structured, task-based interviews (Goldin 2000) will be used in the first stage of the study. Each of the teachers will be interviewed for 1 hour each, 30 minutes for each of the two tasks. A laptop will be available to demonstrate the interactive applets. Each of the 30 minute sections of the interviews will be structured as follows:

- The lesson planning task will be presented.
- Teachers may ask clarification questions.

BEST COPY AVAILABLE

- Teachers will be asked the following sequence of questions:
  - What do you know about the topic?
  - What are your expectations for students?
  - What introductory activity would you use to set the stage for the lesson?
  - What sequence of activities would you plan?
  - How will you know whether students have met your expectations?

In the second stage of the study, lesson plans described by teachers will be analyzed in terms of the level of student mathematical thinking and performance that they facilitate, based on the four-level scheme described in Table 1 (Gadanidis 2002). In the third stage of the study, each teacher will be interviewed for an additional 30 minutes. The analysis of their lesson planning will be shared and questions will be asked to determine: (1) The extent to which the analysis seems appropriate to the teachers; and (2) other insights or explanations they may have that would enrich the analysis. In the last stage of the study, a model will be developed to describe the effect of the availability of interactive applets on the lesson planning of mathematics teachers.

Level	Emphasis
1	Recalling mathematical facts and simple skills.
2	Applying mathematical procedures to solve routine problems.
3	Understanding and explaining mathematical relationships.
4	Extending understanding to new contexts or more general cases.

Table 1. Levels of student thinking

Interaction, Distributed Cognition and Web-based Learning

Penny Ann Garcia, Ph.D.

garcia@uwosh.edu

Abstract: The purpose of this paper is to set the stage for future discussions on an expanded definition of the term *interaction* as applied to web-based instruction. The classic definition may be constraining and reductive in that it does not consider the multiplicity of interactions possible within a web course virtual environment. The field of distributed cognition can illuminate the number of interactions that may be considered. A brief overview of distributed cognition is given. Cole and Engestrom's modified mediated triangle is presented prior to suggesting modification of that triangle to reflect the distribution of cognition over the tools and interactions found in web-based courses.

Introduction

Much attention has been focused on the role of *interaction* in virtual classrooms. Interaction has traditionally been defined by examining two categories – individual and social. Individual interaction has been that which occurs between the student and course information in books, computer programs and lab experiments. Social interaction has come to signify that which occurs between a student and teacher or other students. Most discussion concerning interaction in any distance education class has centered on social interaction. However, due to the increased usage of digital tools by faculty to facilitate the students' grasp of understanding and to the very nature of the web interface which houses the web-based course, a dialogue towards a more robust view of interaction in web-based courses should lead to increased awareness of how the interactions between student or students with the tools routinely used within that course impact the learning experience.

Rationale

Just as the sciences have found richness and interdependency in the study of complex systems, education can expand its view of cognition from the microcosm of the individual to the complexities of distributed cognition. This leads to a renewed interest in the writings of Munsterberg, Luria, Dewey and Vygotsky all of whom recognized the role of interaction in constructing meaning – interaction not only between humans but with tools as well.

Munsterberg (1914) gives one of the first reasoned considerations about distributed cognition. He writes, "A letter, a newspaper…exists outside of the individuals themselves, and yet it intermediates between two or between millions of people in the social group…The book remembers for the social group, and the experiences of the group, objectively recorded in it, shape the social action and the social thought. The letter can connect any distant social neurons; the paper may distribute the excitement from one point of a social group to millions of others. Every objectified expression becomes a social short cut."

Alexandria Luria (1928) asserted that the use of tools and the refinement of these tools was fundamentally unique to humans and stated that these tools "not only radically change his conditions of existence, they even react on him in that they effect a change in him and his psychic condition." These tools included not only basic and advanced technologies but also uniquely human functions such as language. All tools mediate between the person and the task at hand and fundamentally affect human activity.

BEST COPY AVAILABLE

John Dewey echoed this view of the social nature of human development as well. Dewey's (1938) wrote, "Experience does not go on simply inside a person…we live from birth to death in a world of persons and things which in large measure is what it is because of what has been done and transmitted from previous human activities."

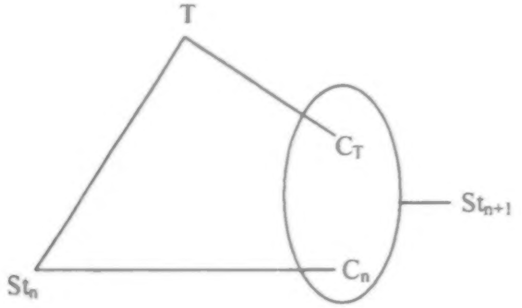
The notion of distributed cognition arises from such consideration of people in action. Certainly activity is enabled by intelligence but the individual does not solely contribute this intelligence. Rather the intellectual resources that shape and enable activity are distributed across people, environments and situations. As Roy Pea (1993) so simply states "…intelligence is accomplished rather than possessed."

In reality, adult students in their daily work interact with a variety of artifacts that significantly enhance their cognitive ability. This cognitive ability, this intelligence, is distributed among other people and tools – cultural artifacts – and, in turn, enables the individual to obtain feedback, gather information, and test hypotheses that extend their mind's potential. As this cognition is distributed, the result obtained is greater than the single whole of the content on which interaction is focused. Instead, each of these distributions across artifacts adds increased dimensions to that content knowledge.

Implications for Web-Based Courses

The traditional classroom and, by extrapolation, the traditional web-based course is founded on the notion of solitary intelligence. Too often, the social, physical, and artifactual surroundings in which cognition takes place have been largely disregarded. Increasingly this view of intelligence has been questioned both by the practitioners of education and the consumers of the education products (or students), business and industry. The observation of what Lave (1988) refers to as Just Plain Folks and experts alike by a wide variety of researchers confirmed that in real-world settings (as opposed to school settings) that the mind rarely works alone. In order to cope with complex activities in an efficient way, human cognition in the real world distributes intelligence among individuals, environments, cultures, symbol systems, tools, and artifacts. In the past much of this distribution was accomplished at a leisurely pace through discussion, shared physical activities, and apprenticeship. Today's society moves at a pace that disables these traditional opportunities for distributed intelligence. Instead, computers and other digital information technologies, while threatening to isolate us even further, also carry the power to create more opportunities for interaction both with the tool and with other humans.

The technologies that deliver web-based courses cannot be viewed as passive neutral delivery systems. These technologies include both the hardware and the software whether it be the web-course building software (e.g. Blackboard or WebCT) or software the students use to construct meaning from the course content. Any technology is a tool that mediates between the subject (learner) and the object (curriculum), creating the classic cultural-historical Vygotsky (1978) mediational triangle. In mediating that transaction, the nature of the object, the subject and the outcome is changed by the technology. In order to truly represent the dynamic nature of this interaction, Cole and Engestrom (1993) added a fourth element, time. In the course of time the two worlds, a student interacting with curriculum delivered through instructor and a student-mediated-by-tool interacting with curriculum, are constantly integrated. This results in the modified mediational triangle shown in figure 1.



BEST COPY AVAILABLE

Figure 1: Instructional mediational triangle symbolizing that new states of the student arise from the integration of information obtained both from the mediated (tool) and direct (instructor) connections between the student and the curriculum. [T, mediating tool; St_n, student's state of knowledge at time *n*; C_T, curriculum as represented via the tool; C_n, curriculum at time *n*; St_{n+1}, emergent new state of student's knowledge at time $n+1$.]

This triangle deals only with the interactions of a single student with a single tool and the curriculum. Within a web-based course, a myriad of tools can be considered which may impact a student's state of knowledge: the student develops a disposition to learning through the ease (or dis-ease) of interaction with the web courseware, the student interacts with various courseware tools, the student interacts with other students via the courseware tools, the student interacts with content via courseware tools and other tools as required by the instructor for the task at hand.

For instance, consider a web-based course delivered in a traditional web-course environment such as WebCT. First students must interact with the primary tool – their local computer – to access the course. Upon entering the virtual course environment, they are asked to make use of the discussion forum tool, the bulletin-board tool, the e-mail tool, the chat tool and the electronic drop box. They need to download and upload materials, convert documents to various formats, and move to a variety of locations specified on the web. Additionally, they may be required to construct a web-page using web publishing software, storyboard their ideas with a thought-processor software, use presentation software to create a synopsis of research, or create an interactive portfolio using a multimedia software. Each of these tools carries with it a means for interacting with the content from different perspectives. Then consider that students may or may not be acting with these software programs solely as individuals; rather, they may take their Inspiration document, email it to colleagues who create their comments in the notes section, and return it to the individual for consideration. Another consideration would be any of the variety of ways that web-based courses may be structured to include a face-to-face component during the semester. All of these actions, these tools, are neither passive nor neutral. Rather, the experience forms a whole that alters students' perceptions of web-based courses, their own ability, that of their instructor, their relationship with other students, and, most importantly, the sum knowledge of the content interacted with during the course duration.

Recognizing that several interactions occur within a virtual classroom leads to a consideration of how the triangle in figure 1 might be modified to reflect the affect of those interactions as it relates to the student's emergent new state of knowledge. Given that there are now multiple tools mediating the curriculum, will that result in a different emergent knowledge state? If those interactions are successful will that knowledge state be enhanced over that of a traditional classroom? If those interactions are perceived as negative by the student, could the knowledge state be actually be less than what would have been achieved by the classic mediated triangle? Figure 2 is presented as a first step towards modeling this state.

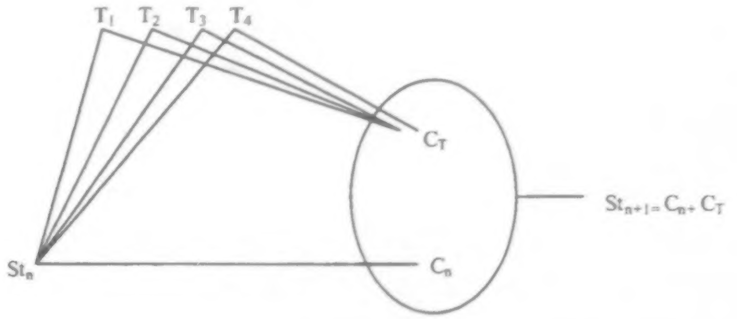


Figure 2: Instructional mediational triangle symbolizing that new states of the student arise from the integration of information obtained from the mediated (tool) and direct (instructor) connections between the student and the curriculum.[T_1,T_2,T_3,T_4 mediating tools; St_n, student's state of knowledge at time *n*; C_T sum curriculum as represented via the mediating tools; C_n, curriculum at time *n*; St_{n+1}, emergent new state of student's knowledge at time $n+1$.]

Conclusion

A dialogue towards enlarging the traditional view of interaction in web-based courses should encompass the recognition of the impact of distributed intelligence in the web environment as well as a careful consideration of the means used to deliver a course on the web. This dialogue can serve to inform the creation of better tools for delivery of web-based courses while providing a basis for reflection on student reactions to the both the web course environment and the instructor. It would allow the examination of the role of the instructor in the virtual environment and how that role may differ significantly from that of the face-to-face classroom. Most importantly, it can lead to recognition of learners as inventors of, and users of, distributed-intelligence-as-tool, rather than as passive receivers of intelligence-as-entity.

Binding Virtual Molecules Sounds Good! : Exploring a Novel Way to Convey Molecular Bonding to Students

Miguel Garcia-Ruiz
School of Cognitive and Computing Sciences
University of Sussex
United Kingdom
miguelga@cogs.susx.ac.uk

Abstract: This paper describes a doctoral research that explores a novel way to convey molecular bonding to students by using a multimodal virtual environment system. Twenty-four chemistry students participated in an exploratory experiment to see if non-speech sounds (musical sounds and natural sound effects that represent information) played as feedback and informative aide in a virtual environment, along with 3D visualization of molecular structure, are useful to support molecular bonding understanding. The experiment consisted of four counterbalanced conditions where participants bound virtual molecules in a desktop virtual environment by using a 3D mouse and listening to sounds and visualizing molecular structures in stereo, as well as using a plastic model set. Results indicated positive outcomes from usability and performance analyses, where non-speech sounds were useful to support molecular bonding understanding

Introduction

This research concerns the application of auditory display, which is the use of sound properties in computer interfaces to convey information (Kramer, 1994), along with visualization techniques, as a way to support understanding of abstract information, such as molecular bonding. Past research (Salzman et al, 1996) shows that a good medium to present both sound properties and visualization techniques is using a virtual environment (a computer-generated 3D graphical environment where the user interacts with it and its contents). Virtual environments offer a unique way to present information in more than one sensory modality with the possibility to complementing or supplementing each, as well as keeping its users from being passive observers, where they interact with the virtual environment, and therefore learn by doing.

Molecular bonding is an abstract topic where students have difficulty to understand how two atoms or molecules bind, as well as the bond characteristics, such as its energy and length, and how both characteristics interact. Literature abounds on showing students' misconceptions and misperceptions about molecular bonding and structure (Hapkiewicz, 1991; Peterson et al, 1989, to name some).

This research suggests that non-speech sounds played in a virtual environment can effectively support students' performance of molecular bonding, and therefore enhance its understanding. To convey bonding information, we used in this research two types of non-speech sounds: *earcons* and *auditory icons*. Earcons are musical tones that convey a message (Blattner et al, 1989), and auditory icons are natural sound effects that have a meaning (Gaver, 1986).

Method

To test the idea of using a multimodal virtual environment to convey bonding, we developed three virtual environments that worked as molecular modelers, and conducted an experiment to test them. It consisted of a within-subjects design, and had four counterbalanced conditions. The conditions can be seen in (Tab. 1).

Condition:	*Activity:*
A (Traditional tool used for teaching molecular structure)	Participants bound two molecules using a plastic model set, bond energy and length values appeared on a label attached to the bond.
B (Visual condition)	Participants bound two virtual molecules in the virtual environment, color variations from yellow to red represented bond energy, and participants watched bond length and atom charges.
C (Visual + earcons)	Participants bound two virtual molecules in the virtual environment; earcons represented bond energy (pitch variations of a pure sine tone), and trumpet and piano notes represented atom charges. In addition, participants watched the molecular structure.
D (Visual + auditory icons)	Participants bound two virtual molecules in the virtual environment; auditory icons (changes in pitch of an electric discharge sound) represented bond energy, and sounds of hitting metal and crystal represented atom charges. Furthermore, participants watched the molecular structure.

Table 1: Conditions Used in the Experiment

The molecular structures were different in each condition, and they do not exist in nature. We did this to avoid participants' previous knowledge recalls. The charges used for the bindings were arbitrary.

Participants were twenty-four chemistry undergraduates from first and second-years (twelve women and twelve men with ages ranging 23 years) from Sussex University in England (the entire experiment was conducted there), and were paid for their participation. Participants' answers to verbal questions asked prior to the experiment indicated that all of them had enough knowledge about molecular structure to perform the experiment.

We used pre-questionnaires to get participants' characteristics, and questionnaires with Likert scales and open questions to obtain the system usability at the end of each condition and at the end of each experimental session. In addition, we measured participants' performance by timing each condition and getting participants' errors they made during the binding through computer logs and by videotaping the virtual environment for further analysis.

The experiment ran on a desktop virtual environment system consisting of a SGI O2 workstation. We developed the virtual environment using DIVE (Distributed Interactive Virtual Environment), a virtual environments browser and programming interface. Participants watched the virtual environment in stereo by wearing a pair of NuVision shutter (polarizing) glasses, and listened to the non-speech sounds by wearing a pair of high-fidelity headphones Sennheiser model HD 570. Further, participants manipulated the environment's point of view and the virtual molecules using a six-degrees-of freedom mouse (Spaceball 3003). The complete virtual environment system can be seen in (Fig. 1), and a screenshot of one of the virtual environments is shown in (Fig. 2).

Figure 1: Virtual Environment System

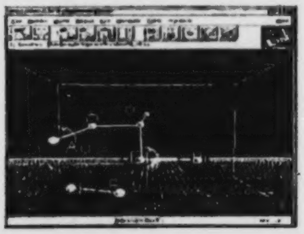

Figure 2: Screenshot of the Virtual Molecules

Participants also used a model set (Fig. 3) to see possible differences between the use of a traditional tool for learning molecular structure and the developed virtual environments.

Figure 3: Plastic Model Set used in the First Condition

Results

Emergent findings obtained from usability questionnaires shown that manipulation of the molecular structures using the plastic model set was easier than using the virtual environments. However, most participants preferred the virtual environment with musical sounds to perform the bonding, and they stated that the virtual environments with sounds provided better feedback (Fig. 4).

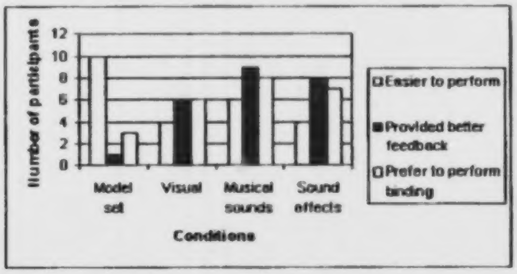

Figure 4: Some Results Obtained From Usability Questionnaires

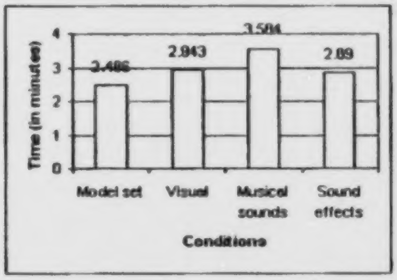

Figure 5: Average of Completion Time in Each Condition

We can see in (Fig. 5) that participants took less time when using the model set. In the conditions with virtual environments, they spent less time when used the virtual environment with sound effects.

Conclusions

The purpose of this paper was to describe preliminary findings of a research on the application of a multimodal virtual environment to support students' performance and understanding of molecular bonding. We carried out an experiment with chemistry students to assess the usability of auditory and visual modalities that represented molecular bonding in a desktop virtual environment. Results showed that although a considerable number of students found the model set easier to manipulate, they preferred the virtual environment with musical sounds to do the bonding. Furthermore, in the conditions that used a virtual environment, participants performed bonding faster in the virtual environment with sound effects.

Accessibility Implications for Multimedia

Multimedia techniques are engaging instructional tools.

> "Everyone benefits from dynamic visual displays and dialog. Well, not everyone. Viewers who are deaf miss all audio content that is not also presented in a visual form. Those who are blind can access only the visual content that is also presented in spoken form. It is not difficult to make video and multimedia products accessible to viewers with sensory impairments, but special considerations should be made at the design phase to assure full access to everyone."
>
> (Burgstahler, 2001)

Electronic accommodations can assist those who are deaf by providing text captioning or links to texts. Millions of Americans have enough hearing loss to affect their ability to hear at a typical volume level. Some people are born deaf or are hard-of-hearing, others experience a hearing loss from accident or illness, and some gradually lose their ability to hear. The elderly are the fastest growing group of individuals who are deaf or hard-of-hearing. Text links allow these people to fully access educational materials with fellow students.

Although captions were developed to make home television accessible to viewers who are deaf and hard-of-hearing, they are important to Internet based video. There are several types of captioning. "Off-line captioning" is developed once the video has been created. The captioner types the captions, which are the recorded on the video image. Captions typically appear on the screen as a group and erase as a group since they do not scroll. Captions are either "open" or "closed." Open captioning appears on the screen wherever the video is presented. It is recommended that products be specifically designed for people with disabilities, for training and education. Closed captions appear only when special equipment, called decoders, are purchased by individuals. "Since 1993 all television sets thirteen inches or larger sold for use in the United States must have built-in decoders." (Burgstahler, 2001)

"Real-time captions" are simultaneously created during a video production. They are most frequently used for live programs such as videoconferences. Similar to a courtroom reporter, a trained stenotypist enters spoken content by typing phonetic codes on a special keyboard that facilitates high-speed transcription. Computer software translates the phonetic codes into text that typically scroll across the bottom of the video production in a continuous motion.

Captioning is usually considered when the video production is complete. Special precautions need to be considered to avoid covering critical visual content with captioning. Burgstahler provides several suggestions for making attractive and functional captions, these include:

- Use one or two lines of text.
- Use a sans serif font, such as Helvetica, and proportional spacing.
- Caption the exact wording of speakers, including slang and grammatical errors. Occasionally a few words may be edited to facilitate reading speed.
- Caption sound effects that contribute to the understanding of the content.
- Use italics to indicate the narrator, off-screen voices, sound effects, and other vital information.
- Synchronize captions with the aural content.
- Avoid changing the location of captions on the screen.

(Burgstahler, 2001)

People who are blind cannot access the visual content of a video production unless there is an audio link available. Once a video product is complete, audio content must be added to the production. When pauses occur in the original production, the audio description voice reads the titles and speakers' names, describes the scenery, objects, and other visual information. Because additional audio description is not of value to other audiences it can be distracting. Audio descriptions are usually not included with a standard video but can be provided as an optional format. Providing this option is particularly important for Internet based videos used in educational programs at all levels. The audio link may be used by those who need this service therefore, it is not distracting to other viewers.

The National Center for Accessible Media (NCAM) is a research and development facility that works to make media accessible to disabled persons, minority-language users and people with low literacy skills. This site also maintains separate types of disabilities. NCAM promotes the use of a Web Access symbol and provides model examples of accessible pages. Creators of web and CD-based multimedia projects need an authoring tool to make their materials accessible to persons with disabilities. NCAM meets this need by providing MAGpie, the ideal authoring environment for multimedia providers who want to add captions, subtitles and audio descriptions to their work. The Trace Research and Development Center provide funding for MAGpie. (http://www.wqbh.org/wqbh/pages/ncam)

MEASUREMENT OF LEARNER ATTITUDES TOWARD INTERNET

Instrument Development: Constructing a valid and reliable instrument was essential for this study (found in Appendix C). Validity is expressed by three different approaches: content validity, criterion-related validity and construct validity, however, each is pertinent to the other. The reliability of an instrument expresses the degree an instrument measures whatever it was set out to measure. The more reliable an instrument, the more confidence the instrument scores obtained would be reproduced when administered again to the same participants (test-re-test).

The instrument used a two position forced choice response to the statements. This instrument forces respondents to choose between the two options provided, Agree or Disagree. This format enhances consistency of responses, makes it easier to tabulate and code the data into a database and is easier and quicker for subjects to respond. However the disadvantages of this format may include constraining or limiting the respondents' choice. Some respondents are uncomfortable in completing a scale with no neutral position. The instrument was also jury validated for content. The instrument was then administered to forty-seven (n=47) undergraduate allied health students. The sample distribution was 70% female and 30% male, 40% White Non-Hispanic, 47% Hispanic, 4% Asian-Pacific Islander, 6% Black-Non Hispanic and 2% American Indian or Alaskan Native. The instrument was reviewed and found to be a homogenous instrument with good internal validity and reliability. The Analysis of Variance (ANOVA) was used to test for differences ($p<.05$) between the group of subjects and the years of computer experience. The subjects grouped based on the following scale: less than 1 year, 1-2 years, 2-5 years and more than 5 years. At this time it was suggested to broaden the years of experience to the following: less than 1 year, 2-5 years, 5-10 years and more than 10 years.

There were no differences in attitudes towards multi media between ethnic backgrounds or gender for the undergraduate allied health students. Ninety-five percent of the respondents reported feeling comfortable using computers, 100% of the females and 86% of the males were comfortable with computers. Sixty-eight percent of the subjects had more than 5 years of experience with computers.

The principle components factor analysis with a varamax rotation identified three factors in addition to measurement of attitudes to assist with the overall assessment of individual reactions to multimedia. The three factors are identified were: 1) Factor one: Learner score for overall Internet delivered multi media as an *effective* learning tool. This factor identified principle components for assessing not only beliefs about multimedia, but also the type of delivery system. 2) Factor two: Learner score of *preference* for courses using Internet delivered multi media. This factor measures learners' preference for learning. The subjects in the study indicated a preference for teacher based delivery over the Internet delivered multi media. 3) Factor three: Learner score for how Internet delivered multi media *enhances* learning. This factor measures attitudes of preference. This is a key underlying assumption that those individuals who perceive that Internet delivered multi media enhances learning are more likely to gain the most advantage from this type of delivery system.

The instrument was rewritten as a final twenty-one-statement instrument with five background and demographic statements A four-point Likert scale was used with a forced choice response: Strongly Agree (SA), Agree (A), Disagree (D), Strongly Disagree (SD). This forced-choice scale omitted the option of neutral or not applicable, which may be troubling to some of the respondents. Four open-ended statements for the respondents to write in their opinion of the strengths, weakness and importance of Internet delivered multi media. This final instrument was used for the remainder of the study.

Subjects: The final target population for this study is undergraduate and graduate students enrolled in Southwest Texas State University statistic courses (n=70). There were three classes of students: Class 1: 22 male and female undergraduate students from various ethnic backgrounds. Class 2: 30 female undergraduate students from various ethnic backgrounds. Class 3: 18 male and female graduate students from various ethnic backgrounds. The total subject demographic information was 74.6% female and 25.4% male, between 19 to 48 years of age although majority of the students were between 19 and 26 years of age, from various ethnic backgrounds. These demographics closely resemble the SWTSU demographic profile.

Study Limitations: This study was affected by the following limitations, sample size, technology, terminology and scoring scale. The sample size (n=70) is a small group. A technological glitch was a factor that may have affected the outcome of the post-test is the technology. The class 1 study may have been tainted by the intervention, an Internet delivered multi media presentation. The technology, Internet access, and RealPlayer plug-ins were not functioning on the day of the pilot study. Class 1 completed the intervention and post-test one day later with out any technological problems. This may have impacted the results of the post-test. The third limitation was the content the Internet delivered multi media segment described, streaming media. This content may have been too abstract for the respondents. The recommendation for future studies would be to use content that is applicable to the audience.

The term "Internet delivered multi media", although defined on the instrument is not a common term and the respondents may not have truly understood the concept when answering the questionnaire. Learners' may be apprehensive about trying new teaching methods especially on-line methods without proper orientation or instruction.

The instrument scoring scale utilized 1 = Strongly Agree to 4=Strongly Disagree. This created some confusion with data interpretation. The scoring scale for the future should be reversed to reflect 4=Strongly Agree to 1=Strongly disagree. This reflects the "normal" thought of a large number being a positive or good result and a low number being a negative or poor result.

Quantitative Results: Numerous surveys have been constructed to measure learners' attitudes towards computers. However, few instruments have been published that measure learners' attitudes towards learning by Internet delivered multi media. This descriptive study constructed an instrument to measure learner's perceptions about Internet delivered multi media.

Of the total sample population for the final instrument administration (n=70), 63 pre and 64 post tests were available for analysis using SPSS software using a factor analysis with a varamax rotation, analysis of variance, chi square and numerous *t*-test. The principle components factor analysis with a varamax rotation identified four factors for the final instrument in addition to measuring attitudes to assist with the overall assessment of individual reactions to multimedia. The four pure constructs are identified :1) Factor one: Learner score for Internet delivered multi media as an

BEST COPY AVAILABLE

effective learning tool. The factor measured the overall reaction to this media as an effective tool for learning. This factor identified principal components for assessing not only beliefs about multimedia, but the type of delivery system. Internet delivered multi media places the responsibility of learning on the learner. 2) Factor two: Learners score of Internet delivered multi media as an *interactive* learning tool. This factor identified the importance of activity versus passivity. This factor plays an important roll in the transfer of learning by this medium. The subjects in the study indicated interaction with a person via Internet delivered multi media is important.3) Factor three: Learner score of their *preference* for courses using Internet delivered multi media. This factor measures learners' preference for learning medium. The subjects in the study indicated a preference for teacher based delivery over the Internet delivered multi media. 4) Factor four: Learner score of how *user friendly* the Internet delivered multi media is. This factor identified and measured the learners' attitudes and perceptions towards the convenience and level of difficulty of this media. Many learners are intimidated by media or find it confusing and these can lead to learning barriers.

The analysis of variance (ANOVA) was used to test for differences ($p < 0.05$) in total attitudes toward multimedia between the two groups for comfort using computers. The data is illustrated in Table 3 below.

Table 3. Differences in Attitude Towards Multimedia

		Sum of Squares	df	Mean Square	F	Sig
Pre Total	Between Groups	309.778	1	309.778	5.402	0.024*
	Within Groups	3211.343	56	57.345		
	Total	3521.121	57			
Post Total	Between Groups	170.477	1	170.477	2.446	0.124
	Within Groups	3553.353	51	69.693		
	Total	3724.830	52			

*Significant difference

There is a significant difference in attitudes towards multimedia between the two comfort groups on the pre-test. However a significant difference does not exist on the post-test. It is assumed the intervention is responsible for changing the subjects' attitudes towards Internet delivered multi media. Such that after viewing the short multi media segment, those uncomfortable with computers now have a higher attitude score for multi media. Cross tabulations were calculated for gender verses computer experience groups. There was no significant association found between gender and experience.

The *t* test for independent samples (a =.05) revealed no significant differences between each of the four groups based upon age, race, and gender for the pre and post totals in the attitude instrument.

Qualitative Results: Qualitative results were obtained from the attitudinal survey. Two trends were apparent from the attitudinal survey data. First, overall student response to the effectiveness of Internet delivered media as a learning tool is favorable. Second, attitudes for preference of courses using Internet delivered multi media are not favorable.

Qualitative research results did not support one of the research questions; do learners find Internet delivered multi media learning more effective than traditional classroom learning? Only 31% believe Internet delivered multi media is as effective as traditional lecture instruction. However, 79% believe Internet delivered multi media is an effective tool for learning before the intervention and 87% after the intervention due to the uncomfortable group changing opinions. Seventy-eight percent believe this media enhances the learning process. 53% enjoy learning through streaming media and 61% will tell others about courses using Internet delivered media.

However, majority of the respondents (90%) preferred an instructor to present the course material, 70% valued Internet interaction with the professor or person teaching the material and 98% valued person-to-person contact. Ninety-one percent believe active student participation is important for learning. However, 49% are excited about learning using this medium and only 39% prefer courses that use Internet delivered multi media. The majority (97%)of the respondents like to learn at times convenient to them.

After the intervention, 76% are not fearful of learning through this medium, nor do they find it confusing (70%) or difficult (70%). A large percentage of the respondents believe this medium is not helpful with retaining (75%) or grasping (59%) difficult concepts.

Only 3% of the respondents reported having less than one year of computer experience. Where as, 70% of the respondents have five or more years of experience. Those with more years of computer experience are more comfortable using computers. This may be responsible for the statistical difference in attitudes towards multimedia between the two comfort groups.

Learners Response To Statements: Students were also given an opportunity on the survey to comment on the strengths, weaknesses, and importance of Internet delivered multi media. Three points stand out from their subjective remarks.

First, the greatest weakness of Internet delivered multi media is the lack of teacher-student interaction and direction. Students may waste precious time searching for answers. In the event technological problems arise, precious time may be wasted searching for the contact person. These issues create discouragement and frustration leading to learning barriers.

The strengths and importance of Internet delivered multi media go hand in hand. Internet delivered multi media is important because it allows institutions to reach people in distant places who may not otherwise have access to the information or content. One of the greatest strengths of this media is repetition. Internet delivered multi media allows students to view the information at times convenient to them and as often as needed. This media also meets the needs of the various learning styles.

Overall the qualitative data provides support that learners' attitudes will change after experiencing an Internet delivered multi media segment. Even after the intervention more students believed this media enhances learning and is an effective learning tool, it did not change their preference for traditional instructor lead courses.

Electronic Portfolios: Effective Assessment Tools in Teacher Education Programs

The School of Education at Northern State University has implemented the electronic portfolio as an assessment tool and as a means of integrating technology throughout teacher education. The electronic portfolio offers a unique opportunity to build preservice teachers' proficiency with technology as well as showcase their expertise in teaching.

The portfolio concept is very popular in education today – and for good reason. First, today's educators have embraced constructivism – the belief that teaching is an active and learner-centered process. This philosophy recognizes that students build their own understanding of the world by using what they already know to interpret new ideas and experiences. Constructivists emphasize not only what students know, but what they do.

Secondly, the growing interest among colleges of education in performance assessment makes a transcript of grades and a score on the National Teachers' Exam (NTE) seem inadequate indicators of competence. A wise person once said: "There is a lot of difference between naming the tools and building the house."

And thirdly, there is still competition for teaching jobs in most areas of the country. It is imperative that prospective teachers be able to demonstrate their teaching competence in concrete ways – to university faculty, to prospective employers, to policy makers at the state and national levels, to parents, the media and the general public.

Why electronic portfolios rather than the paper versions? Electronic portfolios emphasize process as well as product and are multi-sensory in nature, including images, sound, video, text, and multimedia products. It's more fun to see a great bulletin board than to read about it, and it's more effective to hear a university supervisor talking about a preservice teacher's strengths than to read a letter of recommendation. In addition, electronic portfolios facilitate the integration of technology throughout the teacher education program; they provide students with exposure to a wide variety of technology experiences – all in the context of teaching and learning.

The critical phases of portfolio development are collecting, selecting, and reflecting – but the process actually has many phases. Burke, Fogarty, and Belgrad (1994) proposed ten: projecting, collecting, selecting, interjecting, reflecting, inspecting, perfecting, connecting, injecting (and ejecting), and respecting.

As students think about what entries they will collect, how to select those that best convey their abilities, and how to present what they have learned, they are constantly reflecting. Reflective thinking (as defined by Dewey, 1933) is the ability to give serious and persistent consideration to a subject in order to act deliberately and intentionally rather than routinely and impulsively. If teacher educators want preservice teachers to move beyond non-reflective reliance on impulse, tradition, and authority, opportunities for reflection must be provided throughout the teacher education program.

After piloting the use of electronic portfolios with twelve teacher education students during the 1998-1999 academic year, the School of Education at Northern State University began implementing electronic portfolio components into teacher education methods courses. The model used for electronic portfolio implementation solicited proposals from faculty members interested in integrating electronic portfolio components into their methods classes. Faculty received monetary compensation for the creation and integration of electronic portfolio components into their courses.

Each student-created electronic portfolio is original; portfolio components are designed to address one or more of the ISTE National Educational Technology Standards (NETS) and performance indicators for teachers. In addition, students must address each of the five categories of the knowledge base for teacher education at Northern State University: Knowledge of Self as an Individual, Knowledge of Content, Knowledge of the Learner, Knowledge of Pedagogy, and Knowledge of Self as a Teacher and Member of a Learning Community.

Electronic portfolios have been a part of the teacher education programs at Northern State University for four years; current efforts have focused on assessment of the electronic portfolio process and product. Teacher education graduates are asked to complete a self-assessment survey of their technology expertise and their comfort level with technology integration. During their professional semester, preservice teachers showcase their electronic portfolios and receive feedback from university faculty members. Electronic portfolio components are then assessed to determine whether appropriate opportunities have been provided for students to meet the ISTE National Technology Standards (NETS) and performance indicators for teachers as well as the required program outcomes for teacher education graduates of Northern State University.

This presentation will focus on the data collected from the self-assessment surveys as well as the results of the electronic portfolio assessment. Specific components of original student-created electronic portfolios addressing one or more of the ISTE standards and meeting one or more program outcomes will be shared along with accompanying assessment tools, including a newly-developed holistic rubric.

Dr. Constance Geier is an Associate Professor of Education at Northern State University in Aberdeen, South Dakota. She has been at NSU since 1991 and has taught courses in Educational Psychology, Educational Assessment, and Educational Research. She currently serves as NSU's LOFTI Coordinator. LOFTI is a $10 million federal technology challenge grant administered by the United States Department of Education. LOFTI stands for Learning Organizations for Technology Integration, and NSU is one of numerous partners in the five-year grant.

The Changing Role for Universities as Life Long Learner Centres

Ralph Genang, Delft University of Technology, the Netherlands, r.r.m.genang@io.tudelft.nl

Sicco Santema, Delft University of Technology, the Netherlands, s.c.santema@io.tudelft.nl

Abstract:
Universities can become Life Long Learner centres if they adapt quickly to the needs of future knowledge workers. Technology enables universities and research institutions to prepare their organizations to serve and develop future life long learners.
By motivating learners with similar interest to collaborate and innovate, universities will develop stronger ties to the corporate world and their knowledge workers, who will need continuous education in order to effectively compete in the ever changing business world.
This working paper will present you some relevant points and questions. Interested persons can contact the authors for more information about this research program.

Introduction

Today 30% of the total work forces are skill-based workers, workers that need a continuous learning environment in order to do their job efficiently. The US Department of Labour in 2000 forecast that by 2015, 85% of our workforce will be a knowledge-or skill-based worker. How can companies feed all the right skills to the right people acknowledging that most of these future skills don't even exist today?

A primary requirement for any company operating in the knowledge-based economy is to structure individual and organizational learning to create a learning environment amongst its employees, partners and clients. Being able to learn at the speed of change and continuously create and share specific knowledge will be a required skill in order to maintain a competitive advantage over both the near and long term.

Businesses are increasingly operating on a global scale, often in a multi-lingual and multi-cultural environment in different time zones. Due to this growing internationalization, learning at the speed of change and providing employees access to the right knowledge at the right time faces an even more challenging task

Access to Knowledge is one of the Keys

A lot of research and knowledge is available in universities and research centres throughout the world. Many companies, especially SME's do not have the resources to create their own knowledge centers and are in no position to maintain their knowledge centers and create new knowledge.
Employees who have access to a knowledge base where they can share their expertise are stimulated to innovate individually and as a team, yielding increased performance of both individuals and teams, resulting in better performance of the company.
Can Universities and their Research Centers Offer the Necessary Life Long Learning Environments and feed individuals with the necessary knowledge?
In order to contribute to a society that learns at the speed of change, universities will have to learn in close contact with the industry what the purpose of learning is in today's world.

What is the purpose of learning?
1. Learn how to solve problems what is a problem?
2. Learn how to communicate and collaborate in a multi-cultural and global society
3. Learn how to address the impacts of external forces and change

4. Learn how to become a transferor of skills
5. Learn how to stimulate a desire to learn

Learners have to develop three sets of skills that will carry them to a life long learning process

1. Has an ability to learn (Intellectual Capital). The ability to learn has to be coupled to the individual learning style of the student.
2. Knows how to define and solve problems (Creative Capital). They have to be able to apply knowledge to innovate and create solutions to problems
3. Knows how to work with people (Emotional Capital). He has to develop the interpersonal skills to work with a diverse group of people

Today's sixth form students are learning problem solving skills beyond the knowledge based A-levels. They live in a different world than their parents. They know how to use the Internet and other information and communication tools to solve problems quicker and differently and are learning to collaborate and exposed to different learning systems, they grow up in a multi-cultural, global environment, they are capable in multi tasking, they are learning teamwork and leadership skills.
What is the relevance of these skills to a university education as it is currently offered? How important are these skills to a university education and beyond?

Qualifications

Our society is obsessed with the term qualification. So what is a qualification?
Is it the ability to memorize and demonstrate any specific knowledge a qualification for anything? Is it a set of skills required for a job? What job are we qualifying these people for? Will today's jobs still exist tomorrow and visa versa? Is it is an arbitrary designation by the Government, school or university? Is it to measure progress of the learner or of the teacher?

What is the value of today's qualification in an ever-changing world? Since today's economy requires continuous learning being able to effectively compete, the university's role must continue beyond issuing degrees. They'll do that by establishing outreach programs where they will offer short courses and seminars on relevant subjects to the community at large. At the same time universities must encourage in-reach programs by utilizing industry experts, establishing research projects with industry and forming cooperative curriculums with other universities on a global basis.

Tools and technology

Tools have to be created that take advantage of technology and contribute to the ongoing learning process. These tools should give learners easy access to knowledge. They must be able to create their own learning material in constant collaboration with their peers and motivate each other to update their knowledge in a manner so others can benefit from it. The offered continuous learning environment should be based on different learning styles. Some learners prefer to learn by hearing, others by watching or by reading and others by doing.
How will we provide learners with these tools?

In order to be effective, learning must be collaborative, particularly between the learners. The best way to accomplish that via electronic media is through simulations using interactive game theories. Rather than a lecturer, the learning is delivered via a facilitator, which can be an independent third person of one or more of the learners.

Before simulations can take place, universities or research institutions will have to focus on accumulating relevant content based on knowledge available within the institution or within its network. Publications are current carriers of knowledge. But the society does need another carrier that will enable users to access data instantly and remotely.

The carrier does need to shift capture and application of knowledge towards the presence and if possible the future.
Knowledge can only exist in the present. In the past knowledge becomes commodity data and in the future, knowledge becomes intelligence. In the future past knowledge can only be useful if it can be communicated by "insiders" to outsiders through a story reflecting the context of the situation in which the knowledge grew. For future users this knowledge will become commodity data. Capturing this data is relevant for future innovation and the process can only be successful if it is captured in the present.

We believe you cannot learn unless you are emotionally involved! So in order for new knowledge and innovation to grow out of commodity data, the learner, must have a special relationship to the situation, he or she must be emotionally involved and peers must approve his or her experience. This will stimulate the learner to take the effort to capture and share the knowledge and allow it to become commodity data for future purposes.

Delivering learning through a technology media such as the Internet requires a completely different approach than that used in the classroom. The vast majority of Internet based canned courses are created by trying to duplicate a lecturer's role by offering either printed text or in some cases audio or video overlays on a screen. Without an intimate classroom environment and synchronous feedback from the lecturer, this method via the Internet is ineffective, at best.

Both the universities and corporations are introducing technology into their learning centres to lower the costs of training, make the material more relevant and to allow employees, partners and clients to access necessary courses at any time from any place. Up to today it is not clear if these learning centres have the right learning effect.

Building effective courses and creating content to be delivered via the electronic media that can be used by people from different backgrounds and with different interests is a very expensive process initially. However, the results that it will yield will give a rapid return on investment

Example: Business to Business marketing at Delft University of Technology

At Delft University of Technology a first prototype of a new carrier was created over the last five years. There are three different levels of knowledge in this knowledge environment: commodity data, commodity knowledge and new knowledge. (Santema, Genang, 1999) Actually all the bodies of knowledge are just bodies filled with interesting data, or as we call it "commodity" data. As Karl Marx (1957) quoted, a commodity is a mysterious thing, a hieroglyphic – a picture thing, a "beautiful" system now taken to be difficult or impossible to decode. Succeeded in motivating the learners to react on this "commodity" data in order to "learn" it, to deepen it and make their own knowledge of it. But this is not enough. The learner should be able to share his or her knowledge with other learners following the course. Can learners be motivated to state what data they found (and where) and what they did to process it in order to make it knowledge for them. And what happens when they discuss it with other learners. Will they motivate their progress, will they change it, will they convince others and therefore deepen the knowledge they derived from the data? Can they add new knowledge? In order to achieve these learners were rewarded on information and knowledge sharing. Groups of learners were deliberately instructed to look at a subject from different angles and using "knowledge" out of our learning environment or any available medium to substantiate their opinions. The focus of education shifts more to the self-expression and judgment of the learner. (Sakamoto, 1999). There are no instructor-based lectures but student-based lectures. The lectures of the instructor are recorded and his commodity knowledge is now accessible through ICT. Learners can access this data (their perspective) and use it to solve problems. They learn how to find, access and apply relevant knowledge to solve a specific knowledge in collaboration with other users. The time saved by not giving lectures anymore is now for learners. They can discuss face-to-face their learning moments, ideas with other learners or experts. (Representatives of the industry are invited to challenge the learners with future problems, which they do have to solve based on available knowledge, creativity, resulting in future intelligence. Learners prepare their own subjects, they have to use their own hunger to learn to motivate their fellow learners, and they become their own instructors. This is one example how learners are motivated to cooperatively use "content" to create "new knowledge" among the participants. The setup is summarized in (figure 1) The process is baptized Learner-Led-Learning. We are currently studying how we can improve knowledge creation by introducing simulations that will connect learners with different or similar backgrounds and interests to increase innovation. There is a huge interest from the industry to access the current knowledge base and use it as a resource for development and innovation. Some students still access the environment after graduating.

	Classic lectures	**Workshops**
Commodity knowledge **(Teachers perspective)** = **Commodity data** **(Students perspective)**	Learning environment, (Bodies of knowledge)	Learner groups
Teacher **New knowledge** Student	Via - Learners - Www - Instructors	Discussion learners Amongst themselves, and With instructor(s) or Guest speaker(s)
	ONLY ICT	**FACE to FACE**

Figure 1: possibilities for ICT based classrooms, Santema Genang, Delft, 2000

Technology has been a tool during this process enabling learners and instructors to speed up the process of solving a problem by having instant access to relevant knowledge and peers.

Summary: Break the Rules

In order for universities to serve a roll as life learning centers they must address intellectual capital, creative capital and emotional capital in the educational process. Universities have to understand that life long learning not a choice but a requirement in today's economy. Their role is to develop life long learners and provide life long learners with the right tools.

Before that will happen, education has to shift from the past towards the future, towards innovation and creativity. Universities and government must question the value of today's qualifications in an ever-changing world and shift the focus towards evaluating problem solving skills, learning skills and people skills. They will have to prepare their content and structure their organization to allow the establishment of outreach programs where they will offer short courses and seminars on relevant subjects to the community at large. Universities must encourage in-reach programs by utilizing industry experts. They must establish research projects with the industry and form cooperative curriculums with other universities on a global basis.

If universities and research centres succeed in creating, attracting and delivering life long learners and succeed in cooperating with other institutions; universities will play an important role in the future as "centres of knowledge and innovation".

Paulo Freire (Freire 1999) had a message to learners: "I'd like to say to us as educators: poor are those among us who lose their capacity to dream, to create their courage to denounce and announce. Poor are those who, instead of occasionally visiting tomorrow, the future, through a profound engagement with today, with the here and now, poor are those who, instead of making this constant trip to tomorrow, attach themselves to a past of exploration and routine."

Writing Emphasis Goes Online

David C. Gibbs
Department of Mathematics and Computing
University of Wisconsin-Stevens Point
Stevens Point, WI 54481
dgibbs@uwsp.edu

Abstract

This paper describes a unique course residing at the intersection of two movements: an online offering containing a writing emphasis. The course is entitled "Living in the Information Age" and is offered in a department of Computer Information Systems. The learning activities of the online course are described along with their associated writing activities. Several successful strategies are described in some detail.

1 Introduction

The University of Wisconsin Stevens Point has been a leader in technology since the earliest days of networked computing. Technology leaders saw the direction of campus computing, and in 1985, having sought out and established corporate partnerships, succeeded in putting a local area network in place. By the early 1990s, all constituents of the university were regularly using the Internet – well ahead of its time for an institution of its size. Online courses followed as early as 1996, when faculty in the school of education recognized an opportunity to take their coursework to practicing teachers.

Almost a decade earlier, in response to a perceived decline in writing skills, the university began to develop "writing emphasis" courses. A writing emphasis course is typically a discipline-specific course in which students are required to research, compose, and revise text to an extent exceeding a normal offering of the course. The university established a writing emphasis graduation requirement for all freshmen entering in the 1981-82 academic year.

This paper describes a unique course residing at the intersection of the two movements: an online offering containing a writing emphasis. The course is offered by the Computer Information Systems department and is entitled "Living in the Information Age[1]". Several successful strategies are described in some detail.

2 The Learning Environment

The semester long course is taught entirely online (via the Internet) using the courseware *Blackboard* [1]. Blackboard provides instructors with a complete set of online course tools, including discussion forums, folders for course information and assignments, an online gradebook, a virtual classroom, and the ability to manage group interactions. The course described here utilizes each of these features.

3 The Course and its Activities

Students are exposed to course material in three separate ways: by reading and writing, by reading and responding to their classmate's writings in the peer editing process, and by reading and replying to their classmates postings in the online (asynchronous) discussion forums.

---

[1] Course Description: Outline of technological developments occurring in information access and storage, and effects the information revolution is having on everyday life, professions, privacy, security, automation, law, government and employment.

The course is comprised of four principal activities: (1) reading (books and websites) and responding to the readings (by writing or electronic discussions), (2) *e-News* posts (and responses to posts), (3) "*Because-You-Can*" posts (and responses to posts), and (4) *Web-Exercises*. Each activity includes reading and writing.

Readings

The formal readings for the course are intended to prod and provoke the reader. Listed in the order they are examined in the course, they are:

1) ***Technopoly***, by Neil Postman;
2) ***What Will Be***, by Michael Dertouzos;
3) ***Brave New World***, by Aldous Huxley.

Web readings taken from selected URLs are also utilized throughout the course.

A response to a formal reading comes in several forms, varying from a post in a discussion forum to a complete paper. The responses are described in section 4 below.

e-News Posting

An *e-News* post is a current news item of interest that is related to the *Information Age*. The news item may emerge from an online news service, such as Edupage [3], the New York Times Technology page [5], or from another web source. Posting means briefly summarizing the news item, placing the reference (usually a web address) in the appropriate discussion forum along with some provocative questions. Here is an example of an e-news posting (from September 12, 2001) in the discussion forum:

> Use of 911 in cell phones has been talked about for a number of years. Wireless carriers were supposed to have the first phase of the system in place by 1998, and phase 2 was to be established by Oct. 1 of this year.
>
> http://news.cnet.com/news/0-1004-200-7139433.html?tag=mn_hd
>
> But there is an ugly flip side to e911 - the simple fact that identifying the location of the cell phone usually means identifying your location - any time day or night - when calling or not.
>
> Should wireless phones be required to have 911 built-in? Why or why not? Does it represent yet another loss of individual privacy?

Each student must respond (asynchronously) to the questions. Often they are required to return a day or two later and respond to any previous student post.

"*Because-You-Can*" Posting

While similar to an *e-News* posting, a "*Because-You-Can*" (BYC) posting is may be somewhat whimsical. Students are asked to find an example of technology for which the only possible answer to the question "Why would they create that?" is "*Because You Can*".

> Want your hair stimulated and massaged as you brush it? You need the massaging hair brush. It will encourage hair growth by magnetically stimulating your scalp, increasing blood circulation.
>
> I think they should make it with adjustable, programmable settings, though, because my wife and daughter probably have their eye on it and their massaging and detangling needs are way different than mine.
>
> PLEASE tell me what the "blessing" is in this device? And what is the "curse"?

Posting a "BYC" means summarizing the technology and providing the reference (again, usually a URL). Because it is difficult to ask thought-provoking questions in this case, it is sufficient to attempt to establish something *beneficial* (and something *less than beneficial*) about the technology. And then challenge the class to do the same. The point of the exercise, besides having some fun, is to expose the extent to which technology can sometimes presents solutions in search of a problem.

Web-Exercise and Assignment

A web exercise and its assignment will usually involve some exploring of the web leading to a deeper understanding of "Life in the Information Age." Each exercise is organized around a theme [8], such as "Online Education." Sets of questions, accompanied by a series of links, guide the exploration. The written answers to questions are submitted either by e-mail or to a discussion forum established for the exercise.

4 The Writing Assignments

Writing assignments are submitted or exchanged through a variety of techniques, including e-mail (as body text or an attachment), a discussion forum, or the instructor's or the group's drop box.

The types of writing assignments vary from somewhat informal to highly formal. The informal writing assignments include *e-News* and *Because-You-Can* posts and responses. Submitted in a discussion forum created for that purpose, all students are given the opportunity to post, to read, and to respond to the questions raised and their classmates' replies.

Another informal type of writing is found in completing the Web Exercises. Consisting of one or two paragraphs, this writing can be posted in a discussion forum or submitted to the entire class (using a distribution list) or directly to the instructor using e-mail.

Somewhat more formal are responses to readings. These may take the form of answering questions posed by the instructor or posting a "reaction paper." In both cases, students are encouraged to compose text in a word processor making use of spell- and grammar-checking capabilities before copying and pasting into a discussion forum.

The most formal type of writing is the most familiar to college teachers and students, but with some online wrinkles. Given a topic rooted in the readings and discussions, students are asked to address the main points in three or more pages. Peer editing is key. In groups of three, students submit their writing in the digital drop box[2] for their group. Each student will edit two other papers, supplying feedback to their peers using standard word processing strategies. They may insert suggestions directly into the text, add comments using the software's "Insert Comments" ability, or simply use highlighting or font/color changing to draw attention to certain passages or paragraphs. The editor then re-submits the document (using a variation on the filename) to the group's drop box. The author picks up the paper, makes the changes deemed appropriate, and submits it to the instructor's digital drop box. When submitting their final drafts, each student is required to include the peer-edited versions of their papers. The instructor uses the same editing techniques to return marked-up papers to the students.

5 Successful Strategies

The most successful strategies for writing emphasis emerging in this online course are the informal *e-News* and *BYC* posts, the reaction papers, and the longer, more formal papers.

The *e-News* and *Because-You-Can* posts and responses are effective in generating lively electronic discussion, if not quality writing. Students today are well versed in "chatting" and the riposte style that emerges when questioning someone's assumptions. These "discussions" generally remain of high quality due to the implicit moderation provided by the instructor's virtual presence.

Forums for the purpose of discussing reaction papers are restricted to approximately ten students. Each student is required to respond to nine other reactions. Because of the seriousness of issues examined (e.g. personal privacy, ethics of genetic engineering), the dialog taking place here is at an even higher level than the e-News and BYC posts.

According to student evaluations, though they found peer editing of the formal papers a bit of a nuisance, almost all students found it valuable. As writers, they found it valuable in receiving feedback, and as editors, they found it valuable in learning from a classmate's views of the same subject.

6 Summary

Writing emphasis courses were added to the curriculum and graduation requirements in order to improve students' writing skill by increasing the quantity and quality of writing being done. This course presents a variety of writing tasks, from informal to formal, and it does so requiring the interaction of peers. Increasing both time on task and the amount of writing and rewriting with feedback can only assist the goal of improving writing skills.

Somerville, MA
E-Learn@BrandtKurowski.com

Abstract. There are numerous web-based survey instruments for educators that determine needs related to professional development, student results, and school performance. However, people receiving survey results also need simultaneous access to proven solutions to the concerns identified in such surveys. This paper explains a portal tool application of the Semantic Web which pre-configures channels of digital library content based on survey analyses and user profiles. The National Institute for Community Innovations (NICI) has developed the open-source code "Liber," that assists in the use of XML/RDF descriptions of digital resources to customize the presentation of digital library content to the needs of individuals and groups involved in K-12 education. The research and development of Liber has been supported with USDOE, and NSF subgrants and contracts from both NICI and the Vermont Institute for Science, Mathematics and Technology.

Introduction. The World Wide Web (WWW) has enjoyed unparalleled success as a tool for the publishing of digital content, but it remains difficult to find appropriate high quality resources online, even though many exist. Two reasons for this are that (1) the staggering quantity of information on the WWW defies any centralized, human cataloging efforts; and, (2) most WWW information is posted with little attention to information structure, making the cataloging of these resources by computers or humans more difficult. Computer scientists, researchers, and librarians have attempted to address this problem in varying ways, and strategies such as the html "meta" tag and the Dublin Core have been most successful. An effort to improve upon these technologies has led to the creation of the Semantic Web, a multidisciplinary initiative with a structure that allows machines to process information for accessibility of web content.

The core of the Semantic Web is the Resource Description Format (RDF), a standard for machine understandable metadata. Because RDF works in such a way as to allow applications to share data, even if they were built independently of one another, the Semantic Web allows catalogs of resources to be built using a decentralized model. Just as anyone can link to any page on the WWW, anyone can describe any resource on the Semantic Web. This allows for the development of intelligent routing of resources to users, based on RDF queries that express a user's interests.

A New Semantic Web Tool: Liber. The Vermont Institute for Science, Mathematics and Technology (VISMT) and the National Institute for Community Innovations (NICI) began piloting the application of the Semantic Web to the field of online education in the fall of 2000. After discussions with leadership from the Dublin Core Metadata Initiative and the W3C Semantic Web activity, we began development of the Liber engine (http://liber.sourceforge.net), now an open-source software application. Liber allows resources to be cataloged using an extensible metadata framework, and presents those resources through an integrated front-end tool.

Liber is a prototype of the application of Semantic Web concepts and technologies to the needs of the educational community. It is a catalog of community-contributed resources that have undergone review by experts and been cataloged by a librarian. At present, Liber uses RDF schemas from Dublin Core and IMS, merging them with custom RDF schemas representing GEM Element Set and NICI's Educational Reform metadata, to form a comprehensive vocabulary for expressing information about resources of interest to educators. Such an approach exhibits some of the principles of metadata as expressed by Duval, Hodgins, Sutton, and Weibel (2002). For example, the *modularity* of the schemas allows different educational groups to use a small set of core elements to tag resources for a wide variety of specialized educational uses. Second, the *namespace* we propose "*edreform:*" adds a new dimension to the existing core data elements available in existing metadata schemas. Third, the *extensibility* of the metadata system produced by Liber allows for an evolution in the vocabularies. Finally, we are proposing a number of *refinements* to concepts that were originally proposed for broader application. For example, we are proposing a scale of "novice to expert" that is commonly used in educational assessment, as a refinement of the dc-ed: audience.

The Liber prototype has powerful ways of searching resources – users can perform simple searches of the metadata, construct complex RDF queries with a simple web interface, or get a list of resources similar to an already discovered resource. With these tools, users can easily traverse the catalog without being confined by disciplinary boundary, intended audience, or other similarly limiting categorizations.

Liber Applications. The first Liber application was developed by NICI under funding from the US Department of Education, and is used to present online resources that are helpful to grantees in addressing the digital divide - disparities in access to online technologies by race, gender, ethnicity, and income. This work resulted in the application currently running at www.digital-equity.org. The PT3 (Preparing Tomorrow's Teachers to Use Technology, www.pt3.org) grant program that funded the work followed our recommendation to establish a metadata working group, and has promulgated an RDF standard at http://www.pt3.org/2002/elements/1.0/elements Following this initial project, in the spring of 2001, under funding from the US Department of Education's technology innovation challenge grant program, NICI began work on a metadata vocabulary to describe educational reform. The prototype educational reform metadata can be viewed at www.edreform.net/metadata.

EdReform Metadata. As we worked to develop the NICI educational reform metadata, we encountered difficulty due to the fact that metadata standards for education are devised from the perspective of practicing education, not researching and improving education. Existing educational metadata standards, such as IEEE LOM and IMS, are useful for cataloging courseware, but criteria of importance to educational improvement, such as urban teacher preparation, equity, and school leadership, are not addressed. Our prototype work demonstrates that existing metadata standards can be integrated, and that additional metadata specific to the needs of educators in the field will have to be added. For example, we have proposed the addition of control vocabulary under a new qualifier we termed systemic values (see http://www.edreform.net/wiki?EducationalReformMetadata/SystemicValues) to describe the beneficiary and mediator of an educational resource. Our intention is to develop an application framework for educational practitioners to propose cataloging terms, and to integrate those terms into both the existing frameworks of cataloging entities and the initiatives of a number of national educational organizations.

Our initial work indicates that this is possible, and we are now preparing to refine and promulgate the educational reform vocabulary, and develop a methodology to allow for the enhancement of the vocabulary based on an analysis of the proposals from the educators using the applications. We believe that this will significantly enhance the ability of field-based educators to use terms and phrases they naturally employ to describe important concepts in order to search for and access information on validated reform strategies and resources. Our goal is to improve the ease and efficiency with which field-based educators locate material on best practices relevant to their priority concerns.

Responsive Dissemination Portals. The second prototype implementation of Liber is under development at www.edreform.net. "Channels" of information are constructed from specific paths in the metadata, which respond to the key phrases and big ideas of expert panels on educational reform. We have thereby extended existing metadata vocabularies (e.g. Dublin Core, LOM) with an EdReform vocabulary, and included a new process of *aggregation* to define topics relevant to K-12 educational reform. These topics, regarded as critical to state and local K12 educators, include ideas such as urban teacher preparation, equity, and technology infusion. We have found that it is at this level of vocabulary that teachers, administrators, educational leaders and other organizational leaders can effectively interact with digital resources. Our proposed mechanism for *aggregation* is a unique addition to the conceptual framework of metadata principles, perhaps as new form of *refinement.* (Duval, et. al., 2002)

The NSF Protocol. Based on the success of these first two prototype implementations of Liber, NICI began collaboration with VISMT to develop a Liber portal for the NSF Funded National Systemic Improvement Initiative Protocol project. VISMT, in collaboration with seven other statewide systemic initiatives (together called the National Systemic Improvement Initiatives consortium), has developed a web-based survey (the "protocol", http://www.nsii.org/survey.cfm). Its purpose is to enable states and local education agencies (LEAs) to self-assess the extent to which systemic reform is established in their organization. Research by Fuhrman, Clune and others (2001) have shown a relationship between the depth and breadth of systemic change and improved student achievement. That portal is currently running at http://catalog.nsii.org and school systems that complete the assessment instrument are offered a responsively configured channel of resources based on the results of the NSSI survey.

NEA Keys. NICI has also developed an online survey instrument in support of educational reform for the National Education Association (NEA) that can be viewed online at www.keysonline.org/DEMO. Over 5000 users in three states have accessed this survey since it went online in the Fall of 2001. Our intention is to apply the architecture underlying the linkages between the interactive catalog and the NSII application to the NEA's application, as well numerous others. We have recently proposed, for NSF digital library funding, to strengthen the prototype, and to extend it to additional applications.

When a NICI survey is taken, factor analyses are performed on groups of survey questions, which calculate mean scores, priority levels, and standard deviations. Based on these calculations, an index is determined within each metadata category (such as school leadership). An application of the metadata to the factor analysis results matches indices with Liber cataloged resources. Furthermore, because respondents' own personal metadata profiles use the same vocabulary as the other digital resources, it can be used to match people and organizations with one another. Thus, we can expand the definition of cataloged resources to extend to individuals, work groups (such as the classroom), school systems, regional and national educational organizations and other learning organizations.

Conclusion. Liber begins to demonstrate the value and scalability of a responsive dissemination system that (a) queries K-12 educators, students, professional developers, teacher education faculty, and educational leadership via a set of web-based surveys. (b) scores surveys using factor analysis, and generates metadata profiles based on the results. (c) catalogues resources by elements, qualifiers, and controlled vocabularies based on factors assessed in the survey , and (d) presents resources to each user or organization in a channel that is pre-configured according to survey results. When accessed as we are describing, the dissemination of digital resources that are coming online now using XML and RDF standards will be "responsive" to learners, teachers, schools and other kinds of groups and organizations.

Functions of an Online Mentoring and Professional Learning Portal

David Gibson
National Institute for Community Innovations
Montpelier, Vermont
Dgibson@vismt.org

Abstract

How does online collaboration work when a learner is in complete control of the dialog with advisors? How can remote advisors provide high quality feedback on work samples and artifacts? This paper discusses the online Professional Learning Portal project underway at the National Institute for Community Innovations, and presents some of the details of the theory and thinking that is guiding the development. The web-based software is part of work by the National Institute for Community Innovations (NICI at http://nici-mc2.org) to develop tools for enhancing preservice education and supporting increased use of technology, especially in Professional Development Schools.

Introduction

The online Personal Learning Planner is a human and machine web-based assistant site that is based on a theory of dialog recently articulated by myself and Anne Friedrichs (Friedrichs, 2000; Friedrchs and Gibson, 2001). The theory of collaborative interaction for learning is consistent with several writers concerned with authenticity, use of technology to create problem-centered learning teams, representation of complex dynamics in educational settings, and online learning. (Carroll, 2000; Gibson, 1999; Gibson & Clarke, 2000; Newmann & Wehlage, 1995; Stiggins, 1997; Wiggins, 1989, NSDC, 2001).

Friedrichs (2000) discusses four distinct dialogue stages that manifest themselves in the Personal Learning Planning process:

1. Sharing Experience: Listening to own and others' inner speech and natural attitude about a skill or concept.
2. Expressing and Examining Diverse Concepts: Recognizing conflicts; analyzing old and new concepts, models and beliefs; working in one's zone of proximal development.
3. Articulatiing Applications and Understandings: Practicing new skills; combining old and new concepts; using others' ideas, using scaffolds to renegotiate understandings.
4. Communicating New Powers and Creations: Celebrating effects of critical analysis

The online Personal Learning Planner (PLP) provides a structure within an online working space with private and public access controlled by the learner to enable the above framework to work among a learner and any group of people serving as critical friends and advisors to the learner. With funding from the U.S. Department of Education under the "Preparing Tomorrow's Teachers to Use Technology" program (http://www.ed.gov/teachtech/). NICI has developed the first version of the PLP as a "critical friends" online space for future teachers who are assembling portfolios of evidence that they meet the standards required for a teaching license. The PLP is designed to assist learners through the processes of:

- Self-assessment of strengths, interests and aspirations

- Planning preservice education learning goals and projects
- Linking goals and projects to valued outcome standards
- Creating original work and sharing the work with others
- Receiving high quality feedback for the improvement of their work
- Documenting and validating the achievement of learning goals
- Assisting in the selection and preparation of exhibits of learning

Future plans for the PLP include many other learner groups such as K12 students and teachers, trainer-of-trainers programs, leadership programs, and groups as learners, for example, school-based action research teams using the site to develop collaborative products and seeking advice from remote experts to shape and validate the group's work.

Rationale

The rationale for building a web-based tool focused on the improvement of preservice teacher work has two parts. First, there is a need for feedback to come from a diverse audience, yet preservice and induction programs sometimes have limited resources and structures that produce scant feedback to aspiring teachers. As a result, an aspiring teacher's work evolves in isolation, perpetuating the general conditions of teaching present in most schools today. A web-based professional network can help overcome isolation, but even more important, it can provide the future teacher with high quality information that might not otherwise be available. The advantages of "anytime, anyplace" access to experts is an obvious benefit of a web-tool.

The second rationale is that there is a need for effective documentation of learning beyond paper and pencil formats. Ideally, documentation should be a record of the decisions as well as the validation of the work produced. In small personalized programs, preservice teachers benefit from many interviews and observation/feedback sessions related to their work, but in many programs, that experience is limited to the last few months of preparation. An online personal learning planner can help create a longitudinal multimedia record of growth and change in an aspiring teacher's skills and capabilities

The sources of inspiration and rationale led us to ask "What does preservice teacher work look like?" "What would happen if we could build a site for the improvement of a future teacher's work?" "Could the principles of personalization and helpful feedback in a professional network assist teacher education programs?" The online Personal Learning Plan is a way to pose answers to these kinds of questions.

Critical Components in the Online Personal Learning Plan

One of the first questions often raised is whether online learning of any kind can truly be personal. Isn't person-to-person the most *personal* way to learn? In fact, isn't online work one of the most *impersonal* kinds of interaction there is between humans? I don't wish to argue these points here. Online learning is here to stay. It brings remote resources to the desktop anytime, anyplace. Yes, it is in its infancy. Yes, it lacks many important features needed for rich human communication, but so does writing, film, video, and even talking. Using new communication tools in learning is a matter of integration and balance and its effectiveness depends mightily on the attributes of both the learner and teacher. In spite of these challenges, online learning is growing and evolving at a rapid pace.

The Online PLP promotes a uniquely learner-centered approach to the challenge of integration and balance of technology in learning. The following basic assumptions guide the thinking behind the NICI - PLP.

Three bases of planning and action for learning

The purposes of learning can be categorized by three domains:

- Institutional priorities – our shared community goals
- Professional priorities – our scholarly traditions and expectations
- Personal priorities – our source of deep meaning

The Learning Cycle

The Online PLP can be a powerful extension and helpmate in the "action research" process of planning, doing, reflecting and consolidating knowledge.

Focus on the learner's work

The learner's productivity and self-efficacy is the ultimate goal of the Online PLP. Work samples are the critical source for evidence of learning, the documentation of progress, and the verification that high standards have been achieved.

Self-Direction and Making Meaning

Learners produce better and are more highly motivated the more they have decision-making power over their learning. Learners gain from posing questions to advisors, and from knowing about, developing and using a variety of learning assets - their strengths, interests, aspirations, community and personal resources. All learning is a matter of making personal meaning out of the alternatives presented in experience.

Flexible Thinking Tools

Learners gain from scaffolding and assistance in stages and types of thinking, for example, divergent thinking, using multiple frameworks and perspectives, and so forth.

Structure and Roles

The online Personal Learning Planner allows all media formats and a multiplicity of linkages among learning goals, projects, and the evidence of attainment of standards of performance. Distinct from electronic portfolios that concentrate on the presentation and storage of completed work, the PLP concentrates on the improvement of work and the documentation of change of work over time.

Three user levels and a server administrator level are provided. Users levels include the Learner, Advisors, and a Program Administrator. The learner is in charge of their PLP. They create or choose goals, link them to standards or other external sources, create work that stands in relationship to the goals, make decisions on when both goals and work will be shared with advisors, and decide when work and goals are to be archived into permanent storage. Learners can make digital collections from their body of completed work. Each collection is presented as a self-contained website in which each work can independently attach reflections, summative evaluation, and new context-setting narrative and graphics.

Advisors are associated with one or more learners. When a learner's goal or work is being shared for critique and feedback, the Advisor can discuss, offer direct edits or validate the goal or work as adequate for its purpose. For example, a goal might be validated as appropriate to completion of a secondary teaching license in science; a piece of work might be validated as evidence of achieving a standard of performance linked to one or more goals. The validation process can be formalized with rubrics or left as narrative, and any rubric can be associated with any piece of work's link as evidence. When a group of advisors scores a work using a common rubric, a summative rubric can be built upon completion of the work.

The Program Administrator can review all Learners and Advisor records, add and delete Learners and Advisors, set defaults on the number of advisors that need to agree in order for validation to be complete, create rubrics, create and edit standards, and make other selections associated with program management. The Server Administrator controls the hardware and communication decisions needed for site maintenance and archiving.

PLP as a Team Tool

The use of the PLP as a team tool assumes that agency for a group operates much like it does for an individual, once internal communication and trust within the group has been developed. Outside reviewers can be invited to become project advisors. The PLP allows anonymous or "tagged" contributions by group members to facilitate both group and individual accountability. As a collaborative tool, the PLP facilitates building a group's history as well as a collection of validated work products.

Abstract: The primary purpose of this paper is to briefly discuss five interaction strategies that can be used in large-scale (more than 30 participants) Web-based trainings. Evaluation data are presented from seven Web-based continuing education workshops conducted with United States Department of Education (USED) Middle School Drug Prevention and School Safety Coordinators (MSCs) that utilized two of these large-scale strategies. Results of the evaluation show that, contrary to the current literature, MSCs who participated in large-scale Web-based trainings were highly satisfied with many aspects of the workshops, including the on-line facilitation. The results point to a need to replicate these findings and to further study additional large-scale interaction strategies in Web-based training and professional development.

Introduction

As organizations begin to explore the use of the Web for conducting training and professional development, the issue of workshop or class size inevitably becomes a topic of discussion and debate. Organizations feel pressure to increase the number of participants enrolled in a Web-based training because the costs of creating such trainings (or converting a face-to-face training to the Web) are high and Web-based training can be structured to handle lots of participants (Boettcher, 1999). Increasing the number of participants in Web-based trainings can be an effective way to more quickly recoup development costs by using similar resources for a training of 100 participants that would normally be used for 30 participants. This approach does, however, run contrary to Ko and Rossen's (2001) findings that it is not possible to have a high level of interaction when more than 40 people participate in a Web-based training. Similarly, Palloff and Pratt (1999) indicate that given the large amount of time needed for facilitators and students to engage in substantive interaction, limiting training size seems to be a logical and necessary strategy to maximize the quality of the training. At issue then is the nature of the interaction strategy utilized and how it is impacted when the number of participants exceeds the original design or violates what the literature tells us is good practice. This paper presents five large-scale interaction strategies that, if used properly, should help minimize the potentially detrimental effects of increasing the number of participants in a Web-based training beyond the suggested maximum threshold.

Large-Scale Interaction Strategies

Large-scale interaction strategies allow a large group of learners (in numbers greater than thirty) to engage in some form of asynchronous discussion with a facilitator or instructor in an online environment. The premise behind the use of such strategies is that the objectives of the training have less to do with personal interaction (such as building a community of learners) and more to do with providing a means of reinforcing various elements from the content of

BEST COPY AVAILABLE

the training. For the purposes of this discussion, the five strategies described below are based on the presence of 100 people participating in a Web-based training that utilizes an asynchronous bulletin board-style Web-based discussion area. In each scenario, all participants have unrestricted access to the content of the training (materials, activities, etc.).

1. *Multi-Group Interaction* – This strategy divides the participants into four groups of twenty-five. Each group has its own discussion area and a single facilitator. Groups are not able to view other groups' discussions during the training, however, all groups engage in the same activities and address similar issues in the discussion areas with regard to the content of the training.

2. *Forum Interaction* – Based on topical interests (or through random assignment), participants are divided into four groups of twenty-five. Each group has its own discussion area and a single facilitator but, unlike the Multi-Group strategy, all groups are able to view other group's discussions during the training. This strategy can help achieve a large number of training objectives by having smaller groups of participants exclusively address certain objectives and by making the results available to all groups.

3. *Sub-Group Interaction* – More analogous to an active/auditor model, this strategy selects twenty-five participants who are provided a discussion area with a facilitator (the active group). The remaining 75 participants have "read-only" access to the active group's discussion area, i.e. they can read all of the discussions but cannot make postings. The selection of the active group can be accomplished through a registration process (some participants may prefer to be an auditor since this requires no interaction on their part) or selection can be done randomly.

4. *Large-Group Interaction* – This strategy provides a single discussion area, with one facilitator, for all 100 participants. As the training progresses and amount of participation in the discussion area increases, additional facilitators join in the discussion as needed to accommodate the increasing number of questions or comments.

5. *Meta-Interaction* – This strategy uses a synthesis approach whereby participants are able to submit questions or comments to a facilitator (which may also involve a small team of assistants) through e-mail or a Web-based form. The questions or comments are synthesized and posted by the facilitator (usually with his/her comments or reactions) to a "read-only" discussion area. Participants can then read the synthesis and continue asking questions or making comments.

The five strategies mentioned in this section just barely scratch the surface of what is possible using various interaction strategies in combination with computer-mediated communication tools. Each strategy also has various benefits and problems (the scope of which is beyond this paper).

The Study

Seven continuing education Web-based trainings were held with between 36 and 95 United States Department of Education (USED) Middle School Drug Prevention and School Safety Coordinators (MSCs). These events were meant to supplement a five-day face-to-face training that MSCs were required to attend at the beginning of their grant. The events lasted for five days, and each provided a more in-depth presentation of topics that were just briefly introduced at the face-to-face training. The first three training events utilized the *Sub-Group Interaction Strategy* (#3), and the remaining four events used the *Large Group Interaction Strategy* (#4). Post-event assessment forms were used to assess various aspects of each of the trainings including overall satisfaction, whether or not participants would recommend the event to other MSCs, satisfaction with the role of the facilitator, and usefulness of the information presented. As shown in Table 1, participants gave consistently high ratings to each of these aspects across each of the events.

Table 1. Participant Ratings Web Events 1-7

	Overall Satisfaction (Mean 1-5)[a]	*Recommend this event to others (Mean 1-5)*[b]	*Satisfaction with facilitator (Mean 1-5)*[a]	*Usefulness of information (Mean 1-4)*[c]
1: Using Existing Data to Inform Prevention Program Selection (N=37)[d]	Mean = 4.11	Mean = 4.39	Mean = 4.19	Mean = 3.32
2: Identifying Priorities and Strategies for Your Prevention Initiative (N=82)[d]	Mean = 4.05	Mean = 4.33	Mean = 3.91	Mean = 3.54
3: Promoting Prevention Through School-Community Partnerships (N=56)[d]	Mean = 4.30	Mean = 4.35	Mean = 4.11	Mean = 3.37
4: Selecting Research-Based Programs for Your School (N=93)[e]	Mean = 4.51	Mean = 4.53	Mean = 4.17	Mean = 3.59
5: Implementing Research-Based Prevention Programs in Schools (N=58)[e]	Mean = 4.45	Mean = 4.40	Mean = 4.36	Mean = 3.47
6: Sustaining Your Prevention Initiative (N=72)[e]	Mean = 4.59	Mean = 4.52	Mean = 4.17	Mean = 3.65
7: Linking Violence & Substance Abuse Prevention to Academic Success (N=96)[e]	Mean = 4.58	Mean = 4.57	Mean = 4.46	Mean = 3.65
OVERALL	**Mean = 4.40**	**Mean = 4.46**	**Mean = 4.20**	**Mean = 3.55**

[a] Based on a scale from Very Dissatisfied (1) to Very Satisfied (5)
[b] Based on a scale from Strongly Recommend They NOT Participate (1) to Strongly Recommend They Participate (5)
[c] Based on a scale from Not at All Useful (1) to Very Useful (4)
[d] Utilized the Sub-Group interaction strategy. Results indicated no significant difference between auditors and active participants
[e] Utilized the Large Group interaction strategy.

Conclusions

Results from independent evaluations of seven Web-based continuing education events utilizing the *Sub-Group Interaction Strategy*, and the *Large Group Interaction Strategy* suggest that, contrary to the current literature, the use of large-scale Web-based trainings does not negatively influence participants overall satisfaction with the event, their willingness to recommend the event to other participants, their satisfaction with the role of the facilitator, or their rating of the usefulness of the information provided in the event. Further research is needed determine whether the additional three large-scale interaction strategies would produce similar results and whether similar results would be obtained for Web-based trainings that are designed to be more dependent on close participant-to-facilitator or participant-to-participant interaction. Also, future research should examine the extent to which the positive results here depended on participants' prior participation in an intensive face-to-face training by comparing participants with and without such an experience.

BUILDING A KNOWLEDGE COMMUNITY AMONG HIGHER EDUCATION INSTITUTIONS

Marycarmen Aguilar and Catherine Gihlstorf
Center for Innovation in Learning
Kenan-Flagler Business School
University of North Carolina – Chapel Hill
USA
CIL@bschool.unc.edu

Abstract: A professor's head holds a wealth of knowledge and experience both tacit and explicit; relating both to their chosen field of study and to their classroom teaching. Our Knowledge Community provides a repository and collaborative environment in which to capture, store and share this knowledge with others. It is a complete on-line, searchable archive featuring teaching resources, teaching best practices, faculty publications and working papers, and multimedia showcases of faculty research. The knowledge community also provides a place for collaborating partner schools to share research, exchange best practices and to leverage the intellectual assets of the collaborating schools. This project is in progress and scheduled for completion in September 2002. The current community contains 5 partner schools with plans to expand the number of schools over the next 4 years.

Project background

Kenan-Flagler Business School of the University of North Carolina (UNC) at Chapel Hill is one of the top worldwide research business institutions worldwide that is always looking to innovate and increase international collaboration among top business schools. Kenan-Flagler Business School promotes, enhances and facilitates collaboration and knowledge sharing internally in the business school as well as with its global partners. The Knowledge Community (KC) project emerged looking to enrich the internal and external knowledge sharing and collaborative goals of the Business School, as well as to improve the business school's efficiency by having in one location a website interface and a dynamic data base easy to integrate with other internal systems in the school, the university system, and with the systems of its global partners. Also, the Knowledge Community facilitates access to the faculty by external sources, and creates a global virtual community for the exchange of research publications and teaching best practices.

The Knowledge Community is designed to include Kenan-Flagler Business School and all its international partners such as the members of the OneMBA consortium and Centers for International Business Education and Research, CIBER schools. OneMBA is a global consortium allying 5 top business schools from around the world: South America, North America, Asia, and Europe. The OneMBA consortium is offering a premier global executive MBA program starting in September 2002. This program involves students from these 5 universities working on virtual global projects, as well as the faculty teams collaborating to design and teach courses for all of the students. One of the main funding sources that makes the OneMBA program possible is the CIBER grant that Kenan-Flagler was awarded this year. As part of the faculty development section in the CIBER OneMBA grant, the Knowledge Community project is designed to support the faculty development efforts of the OneMBA program and bolster recognition of faculty research at the associated partner schools.

The Knowledge Community project will assist the teaching and learning efforts within the consortium by documenting and sharing faculty teaching best practices and learning activities. It also strives to increase the visibility, and reputation of the faculty of partnering schools both within the consortium and externally by publicizing their research activities and areas of expertise. The project will be divided into three sections: a teaching and learning community, a listing of faculty publications and research activities, and a multimedia showcase section.

The Kenan-Flagler Knowledge Community will be a dynamic repository and collaborative environment in which to capture, store and share research and teaching materials about business topics. Through this virtual collaborative environment the faculty members will share and update all their actual research, all working papers and publications, in addition to sharing their teaching best practices, experiences, activities and teaching materials. The KC will be an instrument that will provide all the publications, research and information about the faculty experts and their specific areas of expertise.

Project Description

The Kenan-Flagler Knowledge Community (KC) has been a team effort involving different areas of the school, including: the Office of the Dean, Business School Faculty and students, information technology staff, program directors, marketing and communication areas, instructional designers, international areas, knowledge management experts, potential users and more. The project is led by the Business School's Center for Innovation in Learning, and supported by internal funds and a grant obtained from CIBER. The project's design and planning covers all research and teaching knowledge-sharing needs of the Kenan-Flagler Business School. This also includes the OneMBA consortium goals, and general trends in the field toward learning communities, knowledge management and information technologies. The fist stage in the project plan is for the pilot version to include the research publications and teaching materials from Kenan-Flagler. The next version will be offered to the OneMBA consortium, and the following versions will be shared with CIBER schools and other international partners of the Kenan-Flagler Business School.

The features in this first Kenan-Flagler version will have 6 main sections, divided into 3 functional areas: research, teaching, and multimedia information showcases. This version will have a stand-alone interface and will also provide various services to the Business School external website and other Kenan-Flagler program websites.

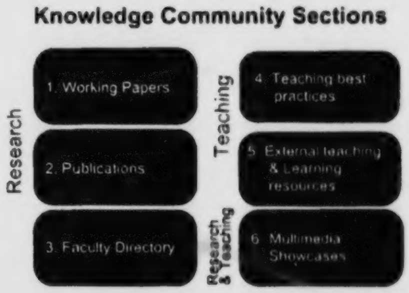

Figure 1: Knowledge Community Sections will cover the functional areas of research publications, teaching best practices and materials and the research multimedia showcases.

Research Sections

The first three functions involve capturing existing publication information on faculty research that currently exists in several non-searchable and searchable venues. This information will be collected on the web in a central, searchable location. A dynamic document-based system will allow information entry, retrieval, and reporting from one central interface. External users will access the information via a web browser. No software beyond this will be required.

Working Papers

Centralized repository of pre-published working papers and abstracts. Searchable via the web and linked from the Kenan-Flagler external web site. Faculty members or designates can maintain their individual

BEST COPY AVAILABLE

entries in this collection. After publication, papers will remain in the archive with the permission of the copyright holder. Currently, these materials reside on individual faculty member web sites, on departmental web sites or on external sites (i.e. SSRN)

Publications

Centralized repository of publications or links to them. Searchable via the web and linked from the Kenan-Flagler external web site. Faculty members or designates can maintain their individual entries in this collection. Currently, these materials reside on individual faculty member web sites, as list entries on the individual faculty member's page, in the faculty directory, in a listing in the annual research report for the Senior Associate Dean, and in a listing in the quarterly Research Newsletter.

Faculty Experts Guide (Faculty Directory)

Central repository for all faculty information with links to resources/papers, personal websites, areas of interest/expertise, contact information, background and recent research.

Searchable via the web and linked from the Kenan-Flagler external web site. Faculty members or designates can maintain their individual entries to this collection. Members of the media, prospective students and other researchers will be the primary users of this section

Teaching Sections

The Teaching sections involve capturing existing best teaching practices from Kenan-Flagler content experts, along with external teaching best practices, and sharing these practices with Kenan Flagler Business School partners and the faculty community. In addition, this section archives existing internal and external teaching resources and tools as a resource to aid faculty in teaching and technology development.

Teaching Best Practices

Centralized repository of Kenan-Flagler Business School faculty and staff teaching best practices. External faculty, specifically from the OneMBA consortium schools and other partner schools may add material to the Kenan-Flagler Business School system once registered in the database. This will allow Kenan-Flagler Business School to expand on an international scale and share the system with its global partners to create a virtual community. This will be searchable via the web and linked from the Kenan-Flagler external web site. Faculty members or Ph.D. students would be the users of this section.

Teaching Resources

The teaching resources section will be a centralized repository of external resources for teaching, including relevant research and best practices. It will include information on Kenan-Flagler Business School's teaching best practices and teaching materials that currently do not exist in any formal or searchable format. At present, some of this information is available at the Program offices or resides with Department Chairs. This information will be available via the web in a central, searchable location.

Multimedia Showcase

This portion of the project highlights the expertise of faculty from various schools. On a rotating basis, select faculty members from each of the schools will be showcased by the Kenan-Flagler Business School and OneMBA consortium. All multimedia showcases will be linked in the marketing website. Faculty will either speak on a current issue or an area of research, or be interviewed. The feature will be delivered via video/audio, audio only, or stills and audio. Each school will have the option of placing this feature on their individual school's pages as well. If feasible, an on-line chat may take place with the speaker during a short designated time or a threaded discussion may be opened to facilitate a dialogue. Faculty members and their schools will receive positive exposure and the program site will gain visitors and attract interest. The first version of the KC will have Kenan-Flagler Business School faculty, Kenan-Flagler guest speakers and faculty of selected global partners.

Data-Base Structure and Technology Tools

The knowledge community project data-base structure is a relation data-base where the two main tables are the Faculty information and the Resources that are written for each faculty member in the community. A best practices table is the third main table in this initial framework. The relationships between tables provide the associations with all the different elements trying to answer all potential questions about the research and teaching materials from the KC. This first structure will be modified and adapted for the following version to include all the feedback from Kenan-Flagler users and international partners.

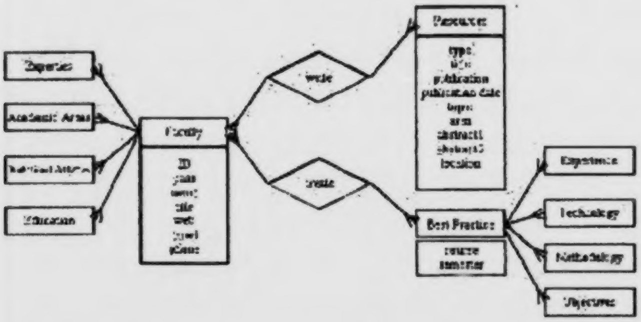

Figure 2: Knowledge Community Relational Data Base Structure

The technology tools that have been used by the team to develop and implement the knowledge community project were selected according to the corporate standards for global information knowledge management systems along with the UNC- Chapel Hill standards. The team will be work with the global partners to assure easy and successful system transfer according to their internal systems. The knowledge community project uses Oracle 8i as a database server and Tomcat 3.2.4/JRun 3.1 as an application server. On the application server, Oracle XDK, Oracle JDBC drivers and JDK would be installed. Additionally, Oracle Client should be installed on the application server to make a connection to the oracle server.

The team is currently working with UNC-Chapel Hill main campus Oracle policies and with the Kenan-Flagler Information Technology administrator to coordinate efficient communication between the different servers, tables and tools used.

Future Challenges

The first version of the KC is on schedule to be up and running at the end of 2002. The challenges confronted during the pilot version have taught us much which can be used for following versions, particularly to include all the lessons learned to increase the success of the future global versions of OneMBA and CIBER. Some of the challenges that the team visualizes for the future versions include: Obtain up to date information from faculty members researchers; Getting and entering the research publications and teaching materials into the system from faculty on a regular basis; Getting faculty to share their teaching best practices, Assuring information quality over quantity .

Knowledge management, global collaboration and knowledge sharing have been some of the university's chief initiatives and challenges in the last decades. For many schools, to open the doors to their latest research initiatives and share their experiences and intellectual production has been a cultural challenge and a difficult goal to achieve. The ones that have accomplished that now enjoy all the benefits and advantages of sharing all their research publications, research initiatives and best practices. This has had a positive impact not only on the organizations' internal cultures, but has also contributed to increasing the visibility of the organizations externally, especially to the various audiences interested in the subjects of business research and business teaching.

The Kenan-Flagler Business School KC project is an example of global collaboration and knowledge sharing. Creating and offering a knowledge community like this will allow all business Faculty from partner institutions to benefit from a virtual community and share their knowledge and experiences through this system in the future.

GEOGRAPHICALLY DISTRIBUTED INTERNATIONAL STUDENT TEAM COLLABORATION

Catherine Gihlstorf and Marycarmen Aguilar
Center for Innovation in Learning
Kenan-Flagler Business School
University of North Carolina – Chapel Hill
United States
CIL@unc.edu

Abstract A partnership of five top-ranked business schools on four continents, this 21-month MBA program develop global leaders and benefits executives through a curriculum that spans business cultures and best practices in Asia, Europe, North and South America. Student teams comprised of one student from each partner school collaborate on projects and coursework in a virtual environment, meeting face-to-face only once every six months. The program's toolbox consists of Blackboard's LMS for asynchronous discussion forums and course material distribution; CentraOne for synchronous collaboration, session recordings and virtual student presentations; and email for asynchronous collaboration and notification. Each student will be geographically distributed. A selection of both web-based synchronous and asynchronous tools was necessary to facilitate the student collaboration. While the program begins in September 2002, the collection of tools has been pilot tested for seven months in another MBA program.

Program Overview

A partnership of 5 top-ranked, international Masters of Business Administration (MBA) programs designed the OneMBA, an Executive MBA degree unlike any existing MBA program. The five partnering schools based in; *North America*; University of North Carolina in Chapel Hill, USA and Monterrey Tech (ITESM) in Monterrey, Mexico; *South America*;, Fundaco Getulio Vargas in Sao Paulo, Brazil; *Asia;* The Chinese University of Hong Kong and *Europe*; Erasmus University-Rotterdam School of Management in Rotterdam, The Netherlands, collaborated to design the program over a year and a half period. The program opened with the inaugural class of approximately 100 students in September 2002.

Each partnering school recruits and contributes students to the program. These students are identified as "local students" or students belonging to a specific partner school. The uniqueness of the program originates with the design of the instruction. Each partnering school designs the basic instruction for their "local" students and a committee of faculty designs a series of globally coordinated courses containing all students from every school. The format for the local instruction remains independent of the other schools. Currently, each school operates on a different schedule and delivery format. The globally coordinated courses however, involve all students and provide identical instruction. Globally coordinated courses begin once every six months with an experiential learning module. All students travel to a designated partner school for the 3 day experiential module. A new business theme organizes each of the 6 month global courses, and the theme, new global student teams and cultural material are introduced during these experiential learning modules. During any 6 month module, a student participates in a series of locally delivered courses as well one team-based, globally coordinated course. This paper focuses on the team-based, globally coordinated courses.

Student Profile/Team Composition

The target student for this program is an accomplished executive with 7-10 years of management experience and responsibility for global activities within his/her respective company. Extensive travel schedules and executive responsibilities functionally eliminate the possibility a traditional two-year full-time MBA program for this audience. The OneMBA program is designed to accommodate part-time executive students with a need for global management and cultural proficiency. Many students possess advanced degrees in areas of study other than business.

All students meet each other "virtually", prior to the debut of the program, by posting short biography pages on a Blackboard course site dedicated to student communication. This site hosts these biographies and all global team discussion forums for the duration of the 21-month program. The first face-to-face meeting between students occurs during a week long "opening week" hosted by the Americans in Washington, D.C. Students participate in cultural exchange activities, group skill-building exercises and engage in learning activities around the first learning module theme: organizational behavior. Global student teams are meticulously selected by a faculty/staff committee to provide representation from each school as well as representation from a variety of professions, industries and quantitative skill levels. Each team contains 5-6 students who participate in a different student team for each module in order to maximize the learning opportunities between colleagues.

Tool Selection

The program's selection of tools resulted from an analysis of our target audience, global coordination challenges and consideration of what each school currently provides. The OneMBA students travel frequently as part of their work responsibilities and accommodate course activities during and after work hours, often in brief time increments such as between meetings or flights. This student group expects superior customer service and support. Partnering schools decided that tool selection would be based primarily on meeting students' needs rather than operating with the lowest common technology denominator among the schools. Each student is required to have a laptop computer with a predefined configuration available for their use.

Team assignments in the globally coordinated courses typically focus on the discussion and analysis of a case study, participation in a simulation or group project preparation and presentation. Geographically dispersed team members represent a time zone span of 12 hours necessitating the availability of an asynchronous communication and collaboration tool. The pilot test of the proposed tools revealed that student of a similar profile to the OneMBA student appreciated the benefits of asynchronous time zone accommodation but realistically had limited time in which to complete assignments and therefore the immediacy of synchronous tools was highly valued. All schools agreed to provide three tools for student collaboration and communication; both asynchronous and synchronous. Student teams were free to use the communication and collaboration method or technology of their choice, but three market leader tools would be provided.

CentraOne

The Centra company located in Massachusetts, USA produces three levels of Internet-based synchronous communication products; E-meeting, Conference and Symposium; increasing in functionality and price with each level. Centra provides ASP services as well as licensing their products as package of a server license and concurrent user licenses. Centra Symposium offers the following features which met the anticipated needs of the program's students: full duplex audio over IP accommodating several hundred participants concurrently, session recording and playback, breakout rooms with the ability to import breakout groups' work back into the main session, application sharing and markup, text chat, whiteboard functionality, web page display and mark-up and one-way video.

As our students travel frequently, the program needed a web-based tool able to perform on a variety of Internet connections, whether from a hotel in Lagos or a corporate network in Las Vegas. The minimum entry requirements for any level of Centra license are a 133 MHz Pentium processor, a microphone and sound card and a 28.8 modem connection to the Internet. This low level of entry satisfied the need of students for flexibility in connecting and participating from a variety work assignments. The recording and playback feature allows students to record their meeting for team members unable to attend or for faculty feedback. Students can also present projects to a team of faculty for evaluation virtually. One way video allows for one group to view the other during the presentation such as the student presenter viewing the faculty member evaluation them.

Virtual office hours become more efficient on-line when faculty can "meet" with more than one student at a time and record the session for those students unable to attend. The application sharing and whiteboard features allow both the instructor and student to share, view and work on a spreadsheet, document or formula at the same time.

The University of North Carolina-Chapel Hill's Kenan-Flagler Business School purchased the Conference product and 10 seats at an educational discount of 50% in December 2001. After a seven month pilot test with a Weekend MBA Human Resources Management class and an online Working Spanish course, the school recommended the product to the OneMBA program with the caveat that the license is upgraded to the Symposium level and 20 additional seats licensed.

The following issues contributed to the recommendation to upgrade. The Conference level license provided excellent duplex voice over IP functionality but limited the number of speaking participants to 5 at any one time. The addition of a sixth student or faculty observer to the meeting necessitated "passing" one of the virtual "microphones" to the extra person and returning it to the originator when the he/she needed to speak again. This "passing the mic" impeded to the smooth flow of conversation. Symposium's inclusion of a whiteboard and integration with Blackboard made it a more appealing choice. The per seat license costs prohibited the purchase of more that 30 total concurrent licenses (seats) but the expectation is that no more than a third of the global student teams will be utilizing Centra Symposium concurrently.

The tool is intended to facilitate student collaboration on their virtual team assignments for the globally coordinated courses. It may also be utilized by any student for their local course collaboration as well. It has also been used as a communication tool for administrative meetings between the partnering schools.

Blackboard

The Blackboard course delivery product incorporates both synchronous and asynchronous tools as well as providing a shell in which to deliver course material. Three of the partnering schools had various levels of Blackboard implementations in use prior to the OneMBA program inception. The remaining partner schools utilized similar delivery products. After considering a number of open market products for course material delivery, the program technology committee selected Blackboard. Since each of the existing Blackboard schools operate a different level of Blackboard license, the OneMBA program itself purchased a level one license from Blackboard, and hosted it in Monterrey, Mexico. As each school maintains their own registration systems, Blackboard's level two or three licenses with registration integration were not needed. The OneMBA program pays the salary of a full-time host master for this server.

A uniform course delivery platform across schools provides students with a consistency and cohesion important when student teams experience the majority of their course interface locally and only 25% of it across the schools. During one module, a student will need to visit only one Blackboard login page for all his/her local and global courses; finding material located consistently within that framework.

Integrated discussion forums with file attachment capabilities provide the base for student team asynchronous collaboration and discussion. Blackboard also allows for the integration and scheduling of Centra Symposium events, therefore students need to enter only one Blackboard site to find all the tools or links to all the tools the program provides. This meets our target audience need for efficiency, consistency and superior support.

Faculty members favor Blackboard for the ability to upload material without knowledge of any scripting or coding language and to do so from any location with an Internet connection.

Email

Email, from either a program provided address or work-related account provides asynchronous communication and collaboration features for virtual teams. Email provides a means for communicating to schedule a virtual meeting or as a backup for other tools or as a means to communicate with faculty members. Each partnering school provides an email account to their "local" students. A roster of all students and clickable email addresses reside in the Student Communication Blackboard course.

Challenges

Support for the globally coordinated courses remains a challenge. Each partner school maintains technology and content support for their local instruction, but the global virtual teams in the coordinated courses fall under no specific school's oversight. The program is experimenting with a global time zone approach to support. The technology support staff at each school troubleshoots technology problems for global course teams during a specific assigned time span. One support email address (support@onemba.org) forwards a help request to the mailboxes of the technology coordinators for each school. The school responsible for that assigned time span (GMT time) answers the request.

Conclusion

Students assigned to global teams for a globally coordinated course meet face to face only once every 6 months. During the interim months, communication and project collaboration relies on a set of synchronous and asynchronous tools provided by the program. Unlike traditional programs, OneMBA students participate both in local courses at their home university as well as in global teams of 5-6 students, with at least one student from each partnering school. Cultural nuances, customs and work and communication styles will need to be negotiated via distance. Part-time executive students accommodate their learning and team collaboration into small time spans and prefer synchronous collaboration.

Areas for further study include the type of tool used for what type of communication/ collaboration, how do the groups dynamics and communication style change if the composition of the team contains more than one student per school, and what alternative technologies and methods, if any, do students use for communication and collaboration beyond what is provided by the program.

European Project:

DELOS (Developing a European eLearning Observation System)

Crsitina Girona
Universitat Oberta de Catalunya
Area of Educational Methodology and Innovation
cgirona@uoc.edu

The Universitat Oberta de Catalunya is participating in the **Delos project** from the beginning of the year 2002 until January 2004.

The project aims at the development, validation and establishment of a sustainable Observation System of experiences and institutions in the **elearning field** to contribute to the decision making process by different stakeholders (European policy makers and market actors). DELOS is a comprehensive and inclusive action that builds convergence and coherence among existing observation & analysis systems and approaches, provided by international organisations, by the various Services and Agencies of the European Union and by other targeted observation projects in European Commission Programmes, such as those in SOCRATES, LEONARDO DA VINCI and IST.

In its first development phase, aspecific analysis of the needs and priorities of the two main groups, the one of the "Information Users" and the other of the "Information Collectors", in Education and Training around the world, is being conducted trough a series of interviews, considering the different specialisations and characteristics of the institutions involved and aiming at the definition of the formulation of a comprehensive map of the different competencies and strengths available in Europe.
The mapping activity will consist in the following tasks:

1) Identifying all different E&T observatory systems, bodies (i.e. actors)
2) Recording the aims, structures and practices of the main E&T observatory systems (i.e. Profiling)
3) Identifying the main stakeholders (users) of the observatory systems
4) Recording the information needs and interests of the main stakeholders

This will allow a definition of the state-of-the-art and will contribute to set up proposals for improvement and define the new observatory.

The institution leading the project is MENON (Belgium). The rest of the project partnership is formed by SCIENTER (Italy), FIM (Germany), CEDEFOP (Greece), LRF (Greece), Swedish Agency for Distance Education (Sweden), EENet (Germany) i EDEN (Hungary).

First project results are expected by September 2002.

The European Commission is supporting the project and sees it as one of the best initiatives for decision makers and policy makers in the field of the use of technology in education.

Developing ICT-facilitators Competencies through a Blended Learning Approach

Lisa Gjedde
Research Program for Media and ICT in a Learning Perspective
Department for Curriculum Research
Danish University of Education
lg@dpu.dk

Abstract: A blended learning approach to a diploma course for in -service teachers, studying to become Pedagogical ICT facilitators, may have implications for their learning process in relation to a multimedia production. Drawing on cases from this diploma course in which a blended learning approach is providing experiential resources for teachers, the development of didactic tools will be related to the teacher's experiential problem oriented learning process.

Introduction

The development of Information and Communication Technology (ICT) has been instrumental in setting the arena for a new learning paradigm, calling for new roles for learner and teacher. It has also pointed to the need for a new set of competencies for the teacher, in order to be able not only to deliver instructions in a subject matter, but also to facilitate the learners' independent learning processes in a number of ways. This paper will explore some of the implications for an blended learning approach to a diploma course for in-service teachers, studying to become Pedagogical ICT facilitators and how they through a process of production of an educational multimedia programme have been challenged with making reflections on the didactics of using and integrating multimedia in their teaching, as well as reflections on the design and communication strategies for presenting it.

This study is based on action research methodology involving 3 classes and a follow up study a a year after the finished course which involves 6 students based on qualitative inquiry with research interviews.

Research questions have emerged that are related to the development of new competencies and a didactics for new media.

How may the pedagogical imagination of the teachers be engaged in the construction of learning environments for their students?

How may this process be supported by a blended learning approach ?

Background

Basic to the didactic approach for the introductory course is a learning cycle involving experience as well as analysis and production, leaving space for reflexivity relating to the learners experiences as well as sharing it with teams of fellow students. The experiential learning cycle has been described by Kolb and others (Kolb 1984) as having four stages: Concrete Experience, Reflective Observation, Abstract Conceptualisation and Active Experimentation. This cycle may happen over a period of time, and include second order cycles within it. Basic to it is a view of learning as a transformation of experience into knowledge. (Kolb 1984)

Part of this experiential approach to a didactics for pedagogical ICT -facilitators, is to use new media in a pedagogical context through a process, which draws on experiential learning methodologies and through an initial multimedia production allows for an articulation of experience and reflection on it.

The use of a project-based multimedia production done by teams that collaborate on the internet, combined with seminars that provide cognitive tools for the reflection on this experiential learning process provides the basic experiences on which to anchor the didactics for the teachers further implementation of a learning new paradigm and the potentials it may offer for the integration of ICT in the curriculum.

It can also provide valuable experiences that may serve as a reference point in the development of a didactics for multimedia, both in the planning process through the use of pedagogical scenarios and the production process. In the design process, it has significance that the students having been through an actual production process, in which they have had to develop a structure reflecting their ideas through a process of articulation. This articulation then enters into a learning cycle as the material for further reflection.

Towards new ways of implementing ICT

The teacher's role in this context is seen as a facilitator and coach rather than as transmitter of knowledge to be passively absorbed by students. One of the ways to facilitate this constructivist approach and build skills and competences that may further this is to focus on the role of individual expression and articulation through a process of design, which is enabling a learning-by-doing approach. It also puts a focus on the need for support of different learning strategies and different preferences for learning. One of the strategies for moving beyond the present limitations of most conference based e-learning systems is to integrate approaches that goes beyond the mere text-based approaches and integrates multi-medial approaches while also allowing for the creation of more ambient environments.

The experiences of the primary and secondary school teachers who were studying to become ICT-facilitators brought a wide background of didactic experiences from the classrooms with children with different needs into the production scope as actual target groups. This also brought forth a number of different design strategies, some of which were explicitly targeting special needs groups as well as focusing on the different intelligences and different preferences of children (Gardner 1993). Some of these designs did represent novel and imaginative ways of engaging children though different web-based programmes, as well as cd-rom based programmes. Some productions did for instance provide an interactive learning environment with a rich media use, involving sound, video and text, each supplementing the other – to provide children with different challenges, based on different preferences or skills. Through this support in web-based learning environments it was made possible for the teachers to free up resources to further assist children in the classroom, with special or different needs. In this way a blended-learning environment afforded differentiated teaching and learning in the primary school.

The teacher's experiences with this design process were carried out in a blended learning environment, constituted by a blend of seminars and a first-class conference, with teams of teacher's planning and developing actual productions. This project based learning environment afforded experiences with e-learning as well as actual meetings with fellow students and the sharing of projects and experiences with projects, which helped anchor the learning into a web-based community.

In this learner centred and project-based course, the communication strategies and scope of the production were be defined and argued for by the students based on their communications strategies for the production thus calling for reflection on the choices made in the production.

It further served to provide the prospective ICT-facilitators with an interpretive and hermeneutic perspective that may transfer into their own perceptions and future roles as catalysts for implementing a new learning paradigm involving the use of ICT within a reflexive pedagogical framework.

The Impact of Technology and Distance Learning on Higher Education

Susan J. Goetz, Ed.D.
MAED via distance learning
The College of St. Catherine
United Stated
Sjgoetz@stkate.edu

Abstract: The promise of distance education to provide education programs that can be undertaken anywhere and at any time is not new. With the rapid advances in technology, higher education today can offer educational services where learners choose the services they need for their own educational and training needs. Higher education is presented with the choice of implementing and delivering quality models where each student receives an educational experience customized to his/her individual learning abilities versus a high-volume or quantity model where the information conveyed is directed to a non-specific, abstract student. In such a high-volume model, the variance among the individuals who constitute the class would have to be ignored. This paper discusses how institutions are resolving the quality-quantity trade-off in their distance-learning, technology-based educational programming while supporting a goal of effectively generating net revenues.

Introduction

The promise of distance education to provide education programs that can be undertaken anywhere and at any time is not new. Correspondence study programs were offered early in the 20th century with great enthusiasm, but they quickly faded from favor because they were perceived as designed around quantity rather than quality.

With the recent advances in technology, higher education today can offer educational programs where students choose the services they need and want for their own educational needs. Students can decide when and where they learn. However, higher education again must visit the choice of implementing and delivering quality programs where each student receives an educational experience customized to his or her individual learning abilities versus a high-volume, quantity programs where the information conveyed is directed to a non-specific, abstract student. In the high-volume model, the range of differences among the individuals who constitute the class would have to be ignored.

History of Correspondence Education

Before the Internet, the only ways to learn outside the classroom were enrolling in correspondence courses, watching educational videos, software designed around specific content, or self-study through reading books and journals. None provide frequent opportunities to interact with teachers and other students – the community building so evident in the classroom (Strehle, 2000).

With the introduction of the GI Bill after World War II in the United States, and an increasing emphasis upon the value of a college degree in the marketplace, student enrollments increased in colleges and universities. This had the effect of creating mass lecture courses, particularly in introductory classes. These mass lecture courses dramatically increased the number of students that could be reached, which severely sacrificed quality for the sake of quantity in higher education. This is a model of education that achieves substantial efficiency – if efficiency is measured in terms of cost per student – but it does so at the expense of quality. There are few teachers who would not tell you that it is virtually impossible to establish a relationship with each student in a large class. However, to compensate for increasing class sizes at the introductory level, students expected reduced class sizes in more advanced coursework. It was hoped that as they moved to higher grades, they would begin to experience small classes resembling seminars. Here efficiency would be sacrificed for quality, and relationship building could be recovered.

Today, however, as the cost of higher education increases more rapidly than public support for higher education, colleges and universities are faced with the necessity to both increase revenues from other sources and to become more cost-efficient. "Budget reductions and general resource constraints have become commonplace, while institutions are being asked to serve increasing numbers of students and constituencies" (Alexander, 2002, p. 1). Such pressures make it difficult for colleges and universities to cut down the size of their classes.

To help generate additional revenues, some colleges and universities are looking at distance education as a way to provide subject-matter experts who deliver programs using the latest technologies. However, if the underlying rationale for utilizing distance education is to generate significant financial revenues, distance learning is doomed to the same fate as correspondence education. Students who found it difficult to travel to specific sites at specified times for their education was attracted to correspondence education. Quality would be maintained through frequent written submissions that would be rigorously critiqued by the subject-matter expert. While such a model prevents student and teacher from meeting face-to-face, a relationship can be built upon frequent correspondence between learner and teacher. This model, as it was designed, proved to be too expensive and did not generate significant net revenues. The process required large amounts by the teacher spent critiquing the students' work. The model then evolved to one where the subject-matter expert designed the correspondence courses, but then turned them over to cheaper sources of labor such as graduate students, adjuncts, and instructors to facilitate the instruction. Even this model proved to be unsuccessful, however, as facilitators found the process too labor intensive. The students' work was not carefully and rigorously critiqued, no relationships were build and maintained, and the demand for correspondence education decreased significantly with a resulting decrease in net revenues generated from this source.

One can see that if distance education is designed with the same goal of generating significant revenues, its future may mirror the experience of correspondence education (Herema & Rogers, 2001).

Definition of Distance Education

Distance education as we know it today is a relatively new technology. Its major goal is to provide education to many kinds of populations, especially to some geographically distributed groups.

Distance education is emerging as a viable and vital force in educational delivery systems in recent years, especially in higher education. Much of the growth comes from a rapidly growing demand for educational opportunities directed toward and designed for some specific target groups (Garrison, 1986; 1987; Gaspar & Thompson, 1995). Just as Amundsen and Bernard (1989) pointed out, "...the definitive characteristic of distance education is the separation between 'teacher' and learner and among learners. As a result, interpersonal communication is not a natural characteristic of distance education" (p. 7). According to Gaspar and Thompson (1995), distance education integrates correspondence, instruction, use of periodicals and teaching aids, mass media, audiovisual lessons, social interactions, computer-assisted instruction, and various technologically-advanced formats. In the perspective of Keegan (1986), distance education has six major features: (a) the separation of teacher and learner, (b) the role of the educational organization, (c) the place of the technological medium, (d) two-way communication, (e) the separation of learner and the learning group, and (f) industrialization. In sum, distance education establishes a system that provides learning opportunities to various groups of learners who have no access to the traditional, higher education institutions.

In addition, according to Bates (1986), there are two basically different approaches of distance education. One is based on structured, pre-programmed learning materials and the other is based on the computers' communications functions. These two approaches have completely distinct philosophies of education. The former is called the black box approach. This approach views the computer as a black box to substitute for the traditional face-to-face (FtF) teacher. Therefore, it is the computer or black box that teaches the students. The frequent example is computer-assisted learning (CAL) software. The latter view is called networks approach. This approach views the computer as a channel of communication between learners and teachers. The frequent example is computer-mediated communication (CMC) systems. Therefore, it is the teacher who teaches the students, only with the computer as a channel of facilitating the two-way communication between teachers and students, online but at a distance and asynchronously. These two approaches are not mutually exclusive. They can be combined to become a powerful medium for distance education. Lauzon and Moore (1989) called the integration of these two approaches the fourth generation distance system that has no barriers of time and place.

The Demand for Distance Education

The diversity in America's higher education institutions has led to a wide variety of approaches to using electronic methods both to enhance on-campus learning and to provide distance learning. Although such on-campus uses are frequently a first priority, distance learning is still growing about 30 percent a year if measured by the number of students.

The development of new technologies is creating a revolution in education and training in the United States. Our on-campus students are already receiving information and educational materials for many of their courses through the Internet. They often communicate with teachers and fellow students by e-mail. Based on a recent survey, universities see technology for on-campus uses as a higher priority than distance learning. The two applications are, in fact, closely linked. The best of the on-campus programs provide a growing source of web-based materials for conversion to distance learning.

When one views the future for distance learning, one must make an assumption about the overall size of the higher education market. Glenn Strehle from the Massachusetts Institute of Technology recently posed the question: "do you believe that the total number of students will not be affected by the increased opportunities for receiving an education through distance learning? If you do, then any growth in distance learning must come from a reduction in the number of students learning in the classroom. Distance learning becomes a substitute for classroom learning." Strehle went on to say: "if, instead, you assume there is a global demand for learning that cannot be met by our campus-based universities, then you come to a different conclusion. Distance learning will increase the number of students and, as a result, enhance real economic growth and create a more educated population" (Strehle, 2000, p. 214).

Based on the number of students enrolled in courses, distance learning is growing at a rate of about 30 percent a year in the United States. A survey by the U.S. Department of Education reported there were about 55,000 distance learning courses with over 1.6 million students enrolled in our 1998 academic year. Since many students were taking more than one distance learning course, the number of actual students was about one-half that number. Looking at more recent estimates, the number of courses may be growing faster than the number of students. This is not surprising as many institutions, particularly public universities, are trying to offer a full curriculum of distance learning courses to be combined with their degree programs.

A survey shows that 90% of public four-year institutions were offering, or expected to offer, distance learning courses by next year. By contrast, only 41 percent of private institutions expected to do so, with many of the remainder being colleges with relatively small enrollments. There is a strong correlation between the size of an institution and its offering of distance learning courses. Ninety-five percent of those institutions with more than 10,000 students, both public and private, expected to be offering some distance learning courses by next year.

About 92 percent of the nation's distance learning students at the undergraduate level, including both four-year and two-year colleges, are taking their courses from a public institution. By contrast with only 8 percent at the undergraduate level, private institutions have 42 percent of the distance learning students at the graduate and professional level. Public institutions have the other 58 percent.

Highly selective private universities do not usually offer distance learning programs toward an undergraduate degree. Their faculties see the campus learning experience as particularly important, including the opportunity for learning in the laboratory. These universities, like MIT, have enhanced many on-campus courses with technology while limiting distance learning to selected graduate and non-degree programs.

There can be a difference in the way that technology is used for undergraduate and graduate education. Undergraduate distance learning programs mostly use text-based Internet delivery and are limited by the bandwidth into the homes of their students. By contrast, it is expected that graduate programs will take greater advantage of streaming video, synchronous two-way conferencing and other uses of broadband technology to create some aspects of the live classroom and seminar. Professional and graduate courses delivered at a distance are expected to grow rapidly. For many, the need to earn credit toward a degree will be less important than the need to develop competence in a subject within a minimum time and at the learner's convenience. Many of the students in graduate and professional courses have access to broadband technology at an institutional location or at their workplace (Strehle, 2000).

What Works in Distance Education

Learning at a distance is not easy for many students. The isolation from both the teacher and other students, the unfamiliar format and need to self-pace their learning can be discouraging. While we are aware of outstanding scholars and public leaders who were largely self-taught, we also recognize that this is very difficult for almost all of us. Motion pictures, television and videos were all predicted to have a major impact on education and found only limited success. Is on-line learning just the latest in a series of new technologies that will fail to meet the educational goals of its advocates? This may be true if we fail to develop frequent opportunities for interaction with the teacher and other students.

Most successful examples seem to have one common factor: the opportunity for students to feel they are part of a community of learners. One successful exception is those educational forms that permit the student to be interactive with the learning, although it is all on-line. Even with these tools, students have to be motivated to learn when using self-paced forms of delivery rather than the rigid schedules of on-campus courses (Strehle, 2000).

The academic performance of distance learning students, relative to on-campus students, provides some assurance that the learning is about the same as measured by tests. Learning at a distance may not be the best way to educate either the next generation of teachers and researchers or those that can benefit from the socializing experience of a campus. For a great many people, however, it is either distance learning or no learning. For others, the sacrifices involved in acquiring on-campus learning may be avoided at some benefit to both the learner and the learning. The search is to identify those methods of distance learning that are achieving success and seeing what works well and what doesn't. We need to bring our research rigor to understanding distance learning.

Summary and Conclusion

What is going to drive the development, growth, and change in distance learning? It will take careful planning with a goal first and foremost of providing quality education to the student. Planning by colleges and universities means responsive policy-making, working with faculty to develop positive attitudes toward distance learning and helping them to adopt the technology, listening to the reactions of the learners. If distance students show a marked preference for one form of delivery over another, there will be colleges and universities who will do it their way. If the free market works the way it was designed to work in the United States, then student attitudes, experiences, and innovation that leads to positive learning outcomes will determine the future of distance learning programs. And in order to create and maintain successful distance education, higher education institutions may have to include many of the techniques of successful businesses, including effective marketing, highly reliable distribution, quality assurance and the ability to quickly adopt what works and quickly drops what doesn't - in short, a focus on the customer rather than the supplier.

Io, Database Driven Web Art-Work

Nan Goggin and Joseph Squier
Narrative Media Program
School of Art and Design
University of Illinois @ Urbana-Champaign
n-goggin@uiuc.edu, j-squier@uiuc.edu

Abstract: Network-based electronic databases are finding expanded application in the worlds of research and commerce. But artists are increasingly putting this tool to new and unexpected uses. This is not a new phenomenon, but rather the latest iteration of a longstanding tradition of artists appropriating technology in unexpected ways. This paper will explain the database engine that drives a project titled *Io*, and discuss the implications of database technologies for future research into new storytelling forms as well as demonstrate the art piece.

io is based on a Greek myth in which a young maiden, who has attracted the amorous attention of Zeus, is punished by being transformed into a calf. She eventually regains her human form by using her hoof to scratch her name in the sand. The story deals with language and writing as fundamental traits of what is means to be human. The io project explores the boundary between consciousness and machine intelligence.The title refers back to the Greek myth of the same name. The piece is an image/text poem comprised of a database of single words, sentences, short paragraphs, images and sounds and a set of rules for analyzing the statements viewers write.

Intoduction

Network-based electronic databases are finding expanded application in the worlds of research and commerce. But artists are increasingly putting this tool to new and unexpected uses. This is not a new phenomenon, but rather the latest iteration of a longstanding tradition of artists appropriating technology in unexpected ways. This paper will explain the database engine that drives a project titled *Io*, and discuss the implications of database technologies for future research into new storytelling forms.

Database technologies hold much the same promise as earlier technologies from the 19th and 20th Centuries. After all, photography as an art form emerged from the discoveries of entrepreneurs intent on capturing the market for mass-produced realistic pictures. The moving image was born in the research laboratory, and was understood initially as simply an improved tool for scientific observation; that is until artists got their hands on the technology and invented the language that today we call cinema. Database technologies, in the hands of artists, may also yield new communication languages. More than just a container for cataloging inventory, customer information, or research data, networked databases have the potential for exploring new constructions and understandings of narrative and storytelling. This presentation will highlight one such example of artists and programmers working collaboratively to appropriate database technology for its poetic rather than its practical application.

Description

io is based on a Greek myth in which a young maiden, who has attracted the amorous attention of Zeus, is punished by being transformed into a calf. She eventually regains her human form by using her hoof to scratch her name in the sand. The story deals with language and writing as fundamental traits of what is means to be human. The io project explores the boundary between consciousness and machine intelligence.artwork they were creating titled *Io*. The title refers back to the Greek myth of the same name. The piece is an image/text poem comprised of a database of single words, sentences, short paragraphs, images and sounds and a set of rules for analyzing the statements viewers write

It's concept is an extension of a simple AI program called ELIZA, which was developed in 1967 by computer scientist Joseph Weisenbaum. In *Io*, unlike ELIZA, the inherent division between audience and author dissolves, and viewers enter into a creative collaboration with the machine." Therefore, *Io* brings us a step closer to realizing the concept of the cyborg; combining human consciousness with machine logic, it becomes part muse and part confidante. Professors Squier and Goggin saw *Io* as a journey into a world of memory and identity, dreams and desires, faith and trust, metaphors and fossil clues.

Project Background

The original *Io* was written several years ago as a Java Applet, which constrained it's interaction and did not make use of current technical advances, We began by exploring the possibility of using programming as a "toolset" to create a better means for people to interact with a machine. At that time, it was only a text-based interactive system. We realized that we could replace the old Java Applet component of *Io* with a database using flat data files.

Our shared interest was to re-design *Io* to communicate using several multimedia elements. Together we devised plans to allow *Io* to respond to particular words typed by the viewer, or to allow the viewer to select text from the screen. We also decided that the user should be given a set of options for viewing the information. *Io* became a platform for inventing a rich interactive system utilizing new technologies. Conceived as a web-based image/text/sound hybrid, the *Io* project explores the boundary between machine intelligence and human consciousness. Utilizing simple artificial intelligence and database concepts, *Io* has been constructed to accept keyboard input and can recognize and respond to a vocabulary of keywords. Each user elicits a different 'performance' of *Io*, creating a multimedia collage of poetic text fragments, images, and audio clips. The resulting narrative addresses issues situated at the frontier dividing flesh and machine: history, memory, vision, and desire.

Project Process

Io involves storage of and access to hundreds of data files–word, text, image and sound files. Each of these data formats are quite different, which means that Io must be able to communicate across these file formats so that it can retrieve, display and update the files quickly. Therefore, scalability and flexibility of software became the most important criteria for selecting our system architecture. MySQL + PHP + Flash was our third architecture model, and became the choice we decided to integrate.

Programs used: Mysql, PHP, Flash, Photoshop, Soundedit,
Hardware: Macintosh g4, Dell

But how does this model work? (a sample scenario)

When a user opens Io [image1: front page] and types a keyword into the input box, {image: interface input box] this word is sent back to the server. This triggers a PHP file named 'readIO.php'. This file checks whether the word is in the database system. It executes a query to repeatedly search for this word in a table. If it finds the word, the PHP file will return a true statement, otherwise it will return as false. If a false value is returned, an error message will be sent back to Io to inform the user that Io cannot understand the word, and the user will be asked to try another word. [image of Io not understanding the word] If a true value is returned, the PHP file will find the corresponding text for that word and temporarily store it in a variable. It then searches for any corresponding images and sounds. Because the image and sound data files are located on the web server rather than in the table, the database merely stores a url pointing the PHP file to the correct file on the web server. All this information, as well as the x and y coordinates for where to place the image, is sent back to Io for display in a browser. As long as the Io gets this message package, it will call upon it's many different functions to show text, display image and play sound.

After finalizing our choice of a system architecture by choosing MySQL as the DBMS for the Io project and with the scripting language being MySQL; we were ready to create the database organization.

Xi Zhang created totally 6 tables in which he labeled 'ww', 'wi', 'ws', 'il' and 'userinfo' respectively. Table below shows the function and schema of different database tables.

. ww was used for storing text information for each keyword
fields: keyWord, outputWord, i

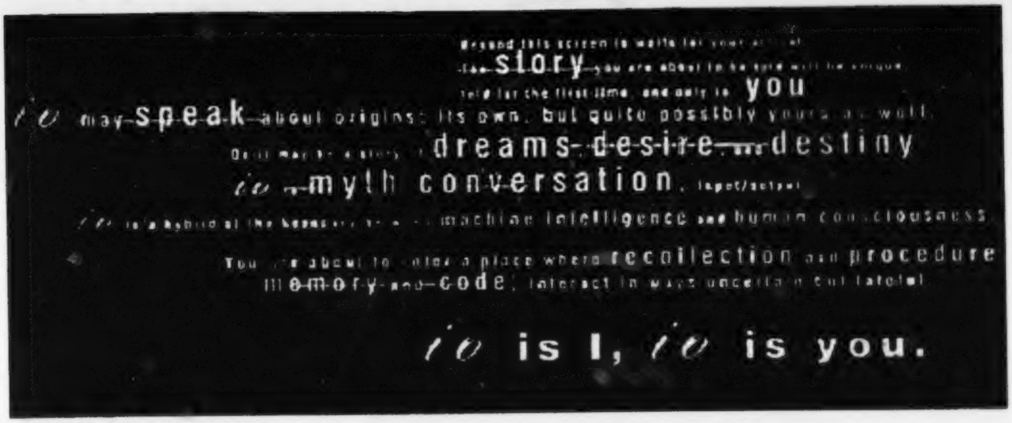
. wi used for storing image url pinter information for each keyword
fields: keyWord, outputImage, imageType, i

. ws used for storing sound url pointer information for each keyword
fields: keyWord, outputSound, i

. il used for storing xy coordinate values for different image type
fields: imageType, x1, y1, x2, y2, x3, y3, x4, y4, x5, y5, x6, y6, x7, y7

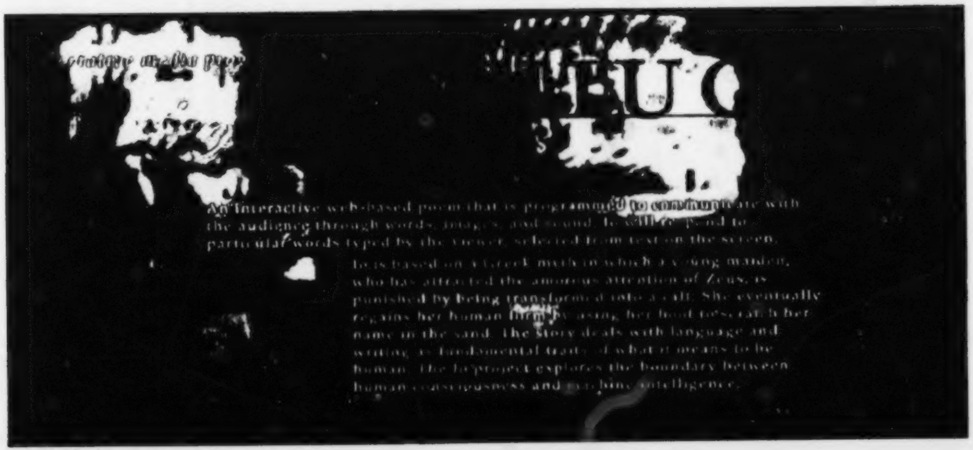
. userinfo was used for storing users's profile
fields: userID, userName, userPass, lastAccess, lastText, userEmail, isNew

PHP accesses these tables and how they relate to each other. For each PHP scripting file, there are a total of 8 files that sit on the server waiting to process incoming requests and output them as Flash files. The 8 type files are:serverCheck.PHP, readUser.PHP, checkUser.PHP, registrateUser.PHP, emailUser.PHP, readIO.PHP and logoutUser.PHP.



Beyond this screen io waits for your arrival.
the story you are about to be told will be unique,
told for the first time, and only to you
io may speak about origins: its own, but quite possibly yours as well.
Or it may be a story of dreams, desire and destiny
io — myth conversation. input/output
io is a hybrid at the boundary between machine intelligence and human consciousness.
You are about to enter a place where recollection and procedure, memory and code, interact in ways uncertain but fateful.

io is I, io is you.



An interactive web-based poem that is programmed to communicate with the audience through words, images, and sound. Io will respond to particular words typed by the viewer, selected from text on the screen.

Io is based on a Greek myth in which a young maiden, who has attracted the amorous attention of Zeus, is punished by being transformed into a calf. She eventually regains her human form by using her hoof to scratch her name in the sand. The story deals with language and writing as fundamental traits of what it means to be human. The Io project explores the boundary between human consciousness and machine intelligence.

***Abstract**: We discuss the results of two e-learning experimental courses carried out in Mexico City which are a part of a research project whose goals are: to experience the teaching learning process through the electronic media via Internet. We worked focused on collaborative working and learning with new pedagogical models based on directed group work by means of assignments, goals, questions and problem solving. Some students manifested anguish as a result of the absence of face-to-face professors; there were differences in personalities, participation and collaboration, aspects that will have to be taken into account for future courses. The conclusion is collaborative work among participants must be promoted, not only letting everybody's interventions to be displayed but also encouraging participants to converse about these courses in public working together in solving problems, elaborating team projects, including evaluating each other.*

Introduction

After the second half of Twenty century problems in educational systems were perceived. Specialists in the subject started to articulate with more emphasis the low effectiveness related to the teacher-centered classes. At the same time, the educational theories were in search of methods and new practices primordially oriented towards a more personalized process of teaching learning, in which the students take the initiative of their own learning. With these goals in mind, the digitalized technology was considered adequate for the innovative education.

Nowadays the cyberspace offers on one hand, the individualized process of teaching learning; on the other, allows the development of certain skills of study and work in group. In the past, an expert professor used to meet these same goals in a traditional setting (a live class, for example), however, the current *modus vivendi* demands to exchange the chalk and blackboard for a different tool; that is to transform the theoretical-conceptual frame and the pedagogic practice. With these modifications, a number of aspects in the learning process will be possible to change, giving as a result a new educative experience.

The use of technology by faculty members

In our university we find a number of middle age professors who avoid the use of computing and Internet systems. The possible reasons are the insufficient amount of computers on campus and the lack of cyber culture among this age group. Besides, the current system of information on campus is still using printed handouts to give instruction to its members. Trying to promote cultural changes in the way of communication in the academic system, a group of professors from UAM-A in the Design Department in collaboration with Humanities Department, started to develop courses in an experimental manner in order to implement changes in the professors' abilities and attitudes. The first one, cost free, was the training of professors in the area of design education via Internet, form April to August 2001. The objectives of the course were: to test the distant learning model and to experience the teaching learning process through the electronic media, to develop the necessary skills to utilize the Internet' s main tools: navigators, email, FTP, distribution lists, chats and navigation browsers; to let the students know the basic characteristics of the computer systems and the necessary electronic infrastructure to access to the Internet. For this experience a limited private web page Discussion Forum was opened, in which the work plan, the location of the reading material and the modalities of participation where annotated. The most difficult aspect was the monitoring of the participants and activities. After four weeks of the course initiation, a decrease in participation was noted. It was necessary to apply the participants a survey to investigate the cause. Technical problems in the professors' offices' computers discouraged the participants from regularly attend in the class. The desertion rate was high, which probably is an indicator of the lack of interest for the use of computers. Other problems inside the campus facilities were related to the system and connections, lack of adequate browser versions, and some associated with a lack of knowledge of the system itself. The students manifested anguish as a result of the absence of face-to-face professors who usually push them to fulfill their obligations and to turn in papers in a given deadline. It is necessary to continue insisting that professors and mentors direct attention to each student in Mexico; to know why someone is behind, to answer all their e- mail messages, to stimulate those who are dropped the class and to pay attention to the causes of desertion. In spite of that, the results were encouraging in the sense that professors became aware of the need to face changes in the way of working and studying. It is desirable to repeat the experience with participants who come from other distant institutions or places and who will have to pay a fee for the course to see if the results of the experiment change.

Teaching face to face with online support

The second experimental course was about reading and written expression. This course, which lasted from September to December 2001, was addressed to graduate students of design. In an experimental manner the participant professors tried to monitor the students, their attitudes and performance through two forms of deliver courses: the traditional one and the e-learning. Our goal was to explore the possibilities to integrate both; to develop an application of the pedagogical model, which was proposed by our research team in which some part was delivery face to face but count on the support of a virtual classroom. We did it with the ***Blackboard*** software (www.blackboard.com) in its free version. This software is an e-learning environment with technical infrastructure and various means of academic support that link technology and pedagogy, such as chat, discussion forum, links to web sites, a place to offer the course material and evaluations and statistics of participation. ***Blackboard*** constitutes one more working option for the e-courses proposed within our group as an element of communication and feedback for students. During the month of December a collaborative practice was made with the purpose of trying to unify the students' opinion about specific and important subjects for the class. The class contribution for team of professors was the experience of an e-class formed by a significant number of students with specific assignments; where differences in personalities, participation and collaboration, creativity, enthusiasm and state of mind were observed.

Trying collaborative working on the virtual environment

Finally, during the period from January through March 2002, we worked in the preparation of the course *Introduction to the e-study in the Improving of Professors*, which took place between June and August. We practice with another e-environment: *Nicenet* software (www.nicenet.org), also free, more limited than *Blackboard*, nevertheless more agile and faster. The collaborative effort among professors to create the course has been quite arduous. We have tried first individual work that later will be reviewed by other members of the team who will subsequently contribute with comments and/or changes to the original text. The first sessions ended up in almost total disagreement. After long hours of discussion and the exchange of texts through the e-mail we thought the work was progressing.

Practice showed that we need to develop certain aptitudes and abilities that in each culture are revealed differently. In our case what is important was the presence of the virtual counselor (conceptually different of the traditional trainer) during all the period, therefore emerged the need of share out the content of the course and that each one of the teachers take the responsibility of their part but maintaining the interaction in all the activities; for example: in the interventions of the forum, in the epistolary exchange, with link suggestions, etc. In this step is precisely when the exigency of the collaborative work between the teachers was expressed.

In particular, Faculty should remain in mutual collaboration with students and among themselves. In this way students get involved and participate actively in their learning management. If we understand the management as a set of processes, actions and procedures aimed to fulfill a number of determined objectives, we could talk about formative self-management. In a distant course the collaborative work among participants must be promoted, not only letting everybody's interventions to be displayed but also encourage participants to opine about these courses in public. Other additional collaborative activities may be working together in solving problems, elaborating team projects, debating subjects democratically, including evaluating each other and learning from the process.

From a cognitive point of view, propitiating the unbalance of the individual's mental models will generate the necessary conditions for learning. Such unbalance may be generated by confronting the individual with two options related to the use of computers: databases supported by hypertext and the synchronic or asynchronic interaction assisted by computer. The former is constituted by the databases supported by the hypertext, such as elibraries, interactive educational material, simulators, on line courses, etc. It is also necessary to pay attention to the need to create new writing systems, which allow a more dynamic reading to get to more amount of information.

Our project is focused on the synchronic or asynchronic interaction assisted by computer to exchange knowledge and dialogue with other members of the class through e-mail, discussion groups, video links, etc. These practices allow to enrich the learning experience in a significant manner since they stimulate not only the acquisition of factual knowledge but also emphasize the o interacting in remote places which facilitates the sharing of common goals.

Conclusions

Our discussion centers on the question: how can we establish a collaborative environment? Some possible answers are making the individual work of students stronger, overcoming isolation, characteristic of crowded live courses, promoting the construction of learning with pedagogical models based on directed group work by means of assignments, goals, questions and problem solving. All these learning activities are based in the principle of learning as a permanent process. Knowledge is acquired in the social process of interaction; the active experience empowers learning. However, it is necessary to evaluate each member of the class to prove that learning has taken place. We have been working on this aspect of distant learning and we hope to organize the last experimental course and from here to draw some conclusions.

Conquering the Digital Divide in Higher Education Attitudes

Valerie Kesner Greenberg
Communication Arts
University of the Incarnate Word
United States
Greenber@universe.uiwtx.edu

Abstract: Defining the digital divide as an important civil rights issue goes beyond social science to make a political and moral statement about the role communications technology plays in fostering a more inclusive and egalitarian America. Students with a good sense of Internet Literacy and who have Internet access, are able to effectively engage in the global village through access to the global economy, meaningful participation in political discourse, and interaction in a social way within the global village. People who refuse to embrace and use computers with Internet access risk being left behind, disconnected from the global village, the political process, and the global, information-driven, market economy. University faculty are primary change agents for inclusion of the Internet in American society, yet many are hesitant to embrace its use in their own classrooms. This paper is a report of a qualitative study which examines the causes for faculty negative attitudes towards technology inclusion in the classroom.

Introduction

Research has shown that a person's beliefs in their own achievement possibilities determine an individual's success in learning. This key personal variable is *self-efficacy* or belief in oneself to achieve goals. Self-efficacy can influence such achievement behaviors as choice of tasks, effort, persistence, and performance. Compared with learners who doubt their capabilities, efficacious students are more likely to engage in tasks, expend effort, persist to overcome difficulties, and perform at higher levels (Bandura, 1997; Pajares, 1995; Schunk, 1996; Zimmerman, 1994).

Within our fields we are experts and as such have an easy attitude towards learning our subject matter. But when the roles are reversed, and we become novices, then the playing field becomes more difficult.

Although research on general skills (e.g., problem solving and decision making) has a long history in cognitive psychology, the study of expertise within a very specific problem domain (e.g., chess, medical diagnosis) is a relatively new research area. A large portion of this work is descriptive; that is, expert behavior is described and often compared to novice behavior. Glaser (1996) summarize characteristics of expertise that are robust and generalizable across a variety of domains:

Teaching recognition of the role differences between experts and novices can help ease expert professors into the unappetizing role of novice learners of technology incorporation into their classrooms.

Learner's beliefs in their efficacy can be enhanced in several ways. One of the most powerful ways is through mastering challenges. A resilient sense of efficacy requires experience in overcoming obstacles through persevering efforts. Another source is through vicarious experiences. Social modeling serves as a way of building a sense of efficacy. Competent models transmit knowledge, skills, and strategies for managing environmental demands. Seeing people similar to oneself succeed by sustained effort raises the observers' beliefs in their own capability.

The third way is through social persuasion-- that is structuring learning activities for learners in ways that bring success and do not place them prematurely in situations where they are likely to fail. Social persuasion can also increase efficacy through correction of negative perceptions concerning subject matter.

Combining these methods might help to provide a classroom atmosphere conducive to a learning experience filled with grace and ease and most especially the intake of knowledge and skills.

Personal variables and environments also affect one another. According to Bandura (1986), human functioning comprises a series of reciprocal interactions between behavioral, environmental, and personal

variables. When learners with high self-efficacy try to complete an academic task in a distracting environment they may increase their concentration (personal variable) to make the environment less distracting. This type of personal influence has been described as *volitional control*
(Corno & Kanfer, 1993)

Perhaps faculty who have experiences other than excellent with technology have personal influence variables which cause them to think more practically about the integration of technology into their teaching methodologies.

The Study

Six faculty members from liberal arts disciplines at two universities were interviewed concerning attitudes towards incorporation of technology into their classrooms. Instructors ranked from assistant professors to full professors between the ages of 32 and 65 . Some had attended several classes in technology incorporation into the classroom while others had not attended any yet. Some instructors used technology (defined as electronic teaching materials or assignments which included overhead transparencies, online projection systems, Internet research tools, web based postings and chats, and the electronic learning service, Blackboard) heavily-- on a daily basis, while one instructor had never used any of these devices. Most used technology moderately to replace previous versions of non electronic instructional tools, such as paper handouts.

Findings

From interviews and observations conclusions were drawn as to the extent and nature of faculty avoidance of technology use. For many, the increased effort necessary to incorporate technology into their class room did not equate to the amount of noticeable improvement in student learning and interaction with presented materials. F says that after spending many hours posting material normally presented as hard copy handouts, his students told him that they preferred the non electronic version of the material. Many faculty declined workshops or tutorials based on anxiety concerns with appearing inexperienced or foolish in their classrooms, a domain in which they normally are the "expert". Experts and novices learn in different fashions, thus feeling inexperienced at mastering new material felt uneasy to the instructors. C states that many faculty in the blackboard (electronic learning environment) workshops she teaches express a fear of failure and avoidance of domains other than their own subject manner of which they are expert, " What is really interesting is that in a sense this is a real role reversal . Here they are the expert in their field, they have a doctorate, they know their fields backwards and forwards. Usually, it has been a long time since they have been in school. And now they are in a class where they know very little. It can totally overwhelm someone."

No wonder then, that a novice in the field of teaching with technology might experience overwhelming feelings of defeat when trying to incorporate the necessary skills to radically change teaching habits.

Novice technology users teaching in the classroom begin to experience a role reversal or what G referred to as "walking in our students' shoes" with feelings of helplessness and sensations of being overwhelmed with incompetence and low skill abilities to complete assigned tasks.

Conclusions

In order to gain the self confidence necessary to believe that one can absorb and effectively complete the "how" of any learning goal, a student must obtain high levels of self-efficacy necessary to succeed in completion of the task.

Our level of self-efficacy influences the choices we make, the effort we put forth, how long we persist when we confront obstacles and how we feel if we fail.

Belief in one's personal efficacy spurs our actions. Unless people believe that they can produce desired effects by their actions, they have little confidence that they will achieve their goal. Self-efficacy buffers the learner's disappointments with failure and provides an unshakable belief in their personal efficacy and a firm belief in the worth of what they are doing. This powerful internal resource enables them to withstand adversity. The slow inclusion of paced innovative additions to classroom technology can help instructors overcome fears of being non-expert. As more technology is placed within their teaching regime, a comfortable level and sense of what is appropriate for their teaching style and what is inconsequential should emerge, raising confidence levels. As confidence is increased, so is usage. When instructors feel competent with the value and competence of their skill level they will begin to model and encourage use among their students of the tools necessary to begin bridging the digital divide.

Multimedia Instruccional Design *VS* Learning Objects Development
A dynamic process of educational content creation in Open and Distance Learning

Albert Sangrà, Academic director and Director of Edu Lab (UOC)
Lourdes Guàrdia, Director of Multimedia Instructional Design Dp. (UOC)

Tel: 34-932532300 http://www.uoc.es

The role of Multimedia Instructional Design (MID) applied to the new information and communication technologies substantially changes in those teaching and learning models based on Open and Distance Learning.

> An intrinsic link exists between instructional design (ID) and open distance learning (ODL). Their inextricability in the real world raises specific problems of interest in the field of ID. In no other teaching/learning situation is ID essential as in ODL. The conditions of ODL make it a necessity to have long-term instructional planning, cost, analysis, curriculum and course development, instructional materials development and maintenance, delivery plans, and detailed evaluation rules. Without all of these components, DL simply could not happen. It took some time for this necessity to be acknowledged, as can be seen in the history of ODL. (Bourdeau, J. and Bates, T.)

The term *Instructional Design* is usually used to describe the process in which:

- the learning needs and the environment where they will manifest are analysed;
- training needs are defined;
- the most appropriate resources regarding the learning processes are chosen:
- contents and activities are developed;
- evaluation is designed

However, this concept becomes much wider when referring to ODL. We are nowadays facing the challenge of making good use of the possibilities of multimedia technologies in order to offer much more significant learning than those which traditional educational materials would facilitate; so, it is necessary to take into account all the elements intervening in the instructional design of a concrete training action for ODL. In that sense, the coherence of the materials and the teaching strategy, together with the functionalities of the virtual environment and the relations that will be developed will be fundamental.

Gillespie (1995) recently contented that a well-designed piece of courseware should incorporate the most appropriate aspects of each learning theory (Phillips, R.):

> This is what we as instruction and learning environment designers ought to be striving for, using our expertise and knowledge of behaviourist, cognitive, and constructivist learning theory to combine with expertise in other disciplines (multimedia, human factors, systems engineering, telecommunications, etc.) to design and deliver the most appropriate solutions for our performance improvement and learning situations.

The ideal piece of courseware incorporates the most appropriate parts of both theories, and the balance will be different for every application.

Our experience in distance learning has shown us how important it is to have well structured materials which are designed from a pedagogical point of view, and keeping in mind what, how and when we want to teach or encourage learning.

Dr. Michael Moore -the president of American Center for the Study of Distance Education (ACSDE)- said in his last conference, in June 2001, in Barcelona (at UOC) *"It's necessary to invest more in design than in technology...the learning outcomes are related also to design of the course and the tutor's support"*

This implies training the authors (usually specialists in a field of science or other areas of study) in how to elaborate teaching material for distance learning.

Thus, some professors may need to expand their own material or prepare new one. This implies, again a training task, centred not only in the understanding of the distance teaching-learning process, but also in the knowledge of resources and tools to make the elaboration of material easier.

This need will force many distance learning institutions to plan the creation of tools which allow tutoring and continuous training for teachers and authors; so that learning objectives in an ODL model in which technology brings us new opportunities, are fully guaranteed.

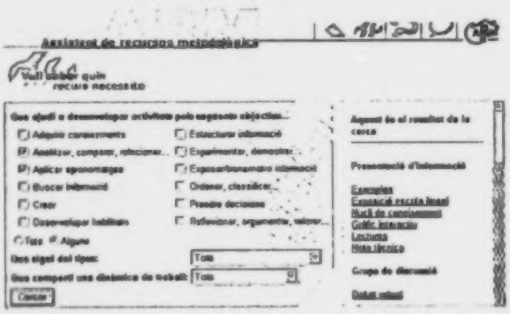
BEST COPY AVAILABLE

In our case, at Universitat Oberta de Catalunya (UOC), the ARM (Methodological Resources Assistant) was created to answer the above mentioned needs.

1. What is the ARM?

The ARM is a system for the design and elaboration of methodological resources adapted to different objectives and training needs, in a virtual learning environment.

Its aim is to provide a wide range of distance learning methodological resources as well as tools to facilitate material creation, for professors and authors.



2. What can be found there?

The ARM enables:

- Looking for resources: The user can carry out resource or activity type searches from different criteria using a very simple and intuitive interface.
- Accessing to a concrete resource report by selecting its name.
- Acquiring ideas/Offering ideas. This is a project open to all the new incoming resources and activities that may appear with new needs.
- Consulting methodological aspects.
- Creating instructional activities.
- Giving guidelines or advice of pedagogical use

See in detail each chapter:

- Looking for resources

The user can carry out resource or activity type searches from different criteria using a very simple and intuitive interface. The route that takes the users to the resources that would best fit their needs depends on the desired objectives, the kind of activity and the work dynamics they prefer.

- Accessing to a concrete resource report by selecting its name

Every resource report provides information about the typology or category that the resource belongs to, the goals that can be reached with it or the activity given; the resource description – structure, stages, functioning, etc.-; the application – guidelines or directions to improve the possibilities the resource offers; the work dynamics to follow; the view of concrete examples; the elaboration guidelines for the resource; the bibliography reference; and templates and programs to create resources easier.

- Acquiring ideas/Offering ideas

Our idea is to fulfil the potential users' needs in advance. This is a project open to all the new incoming resources and activities that may appear with new needs.

This is why we offer a double use: you can access ARM knowing what you want, and therefore going directly to a concrete resource or you may access to look for new ideas. Every resource has got concrete examples that will help you to decide what you want.

- Consulting methodological aspects.

The functional ARM includes important aspects such as strategy offers to teachers and authors in order to define goals, select contents, make guidelines for material, follow style indications, etc. You can access to ARM methodological contents in various ways: as a course to be followed or as a consulting space for concrete questions.

- Creating activities: the programs and templates

ARM objectives are not only to select resources but to facilitate the creation of new activities. In order to achieve it when choosing a resource, we can access to a template in the shape of a form or other systems, where the necessary steps to create an activity would be given.

Once the form has been filled in, you can print it out and save the written content before being sent to a general database where the technicians in charge of the activity of implementation would give it the corresponding format.

There is a double aim behind these programs and templates. On the one hand, their aim is to help in creating new activities, and on the other hand, to facilitate their later implementation, given that the model's goal is to ensure that every requirement is met for later implementation.

BEST COPY AVAILABLE

- Giving guidelines or advice of use

We can access the assistant knowing which resource we are looking for and then obtain some guidelines or advice on how to use it in distance learning. Thus, there is a report for every resource with this kind of advice.

3. What is its structure?

The ARM is structured as a system composed of different elements:

- A communication space (forum, FAQs, consulting mailbox...)

In this space the users find a forum and a mailbox for asking questions about or giving their opinion on what ARM provides.

- Help or Guidance about methodological aspects

It helps methodological design explaining, for example, what we are referring to when talking about objectives, how to take decisions about what resources to use, how the learning guide is structured, what is evaluation and how to treat it.

- The searching form

The searching form is the tool that helps the professor or the author to know the best resource features for their material elaboration. The result of the searches is a list of the resources that best suit the user's requirements.

- The resource reports

From the result list you can access to the resource reports, which include the previously mentioned sections. The main aspects are the guidelines for resource elaboration, the examples and the elaboration templates and tool that make the process easier for the author.

> The recent growth of the field of interactive multimedia may be attributed in part to the availability of courseware authoring, which gives the course-ware developer who has no expertise in programming in high-level languages the ability to control the full range of presentation functions.(Inglis, A., Ling, P. and Josten, V.)

4. What's the future?

After working in this system of design for the last two years, we are just starting and adding a new concept of how to conceptualise learning materials in terms of educational knowledge management (EKM). In this sense, the instructional design is based on learning objects and consists in structuring the educational contents thinking of the interactions between users profile, learning resources and the virtual environment.

Also the EKM tries to consider the artificial intelligence techniques in order to get information about students previous knowledge and to assure the interactions between the learning objects, learners and teaching staff offering learning resources, strategies, and contents that the students may need. An analytical model of teachers' cognitive-interactional activities within an experimental reflective teaching situation would be an interesting research to do.

> In order to carry out educational activities successfully, teachers need to draw on a wide variety of knowledge, such as students' knowledge, the curriculum, teaching methods, classroom organisation, educational goals, and subject matter… we focus on the nature of teacher's knowledge of student's knowledge and on the understanding how teachers acquire it in a form that is appropriate to the specific activity in which they are engaged. (1999, Lund, K. Baker, M.)

The EKM system that our institution is planning to implement has a determinant impact in the creation and edition of learning materials, concerning the optimisation and agility of the process, as much as the increase in the security.

Our interest focuses on assuring the structure of the materials and their pedagogical adequacy, lessening production times and guaranteeing that the original work from authors is being delivered in the best condition.

This is the reason why we need to design certain processes and tools which allow us to reach the stated objectives, by generating contents according to the knowledge management system (standardised -tested- and innovative elements) and that which can be presented on different support systems.

The organising axis of all this is the Methodological Resources Assistant, a pedagogical portal for any educational development of the institution that facilitates all the necessary information, tools and guidance for the creation of learning and teaching resources.

Course Development for Distance Learning Using PowerPoint

This paper describes the process and procedures for the development of a distance learning course using PowerPoint as the design software.

Multimedia and Distance Learning for Business in Borovichi, Russia funded by the United States Department of State was a grant to provide course materials for Russian business education. These materials were developed by individuals from Broome Community College, in Binghamton, NY and the American - Russian College of Commerce "InterBiz," in Borovichi, Russia. The materials used in the demonstration course were developed by faculty members at Broome Community College (BCC) in Binghamton, N. Y. Anne Blakeslee, Professor of Business at BCC (Blakeslee_a@sunybroome.edu), was responsible for course content; while Alice McNeely, Director of the Teaching Resource Center (mcneely_a@sunybroome.edu), and myself, George Guba, Multimedia Instructional Designer, organized and designed the technical aspects of the project.

The grant required the trainers from Broome Community College and the instructors from Interbiz College in Borovichi, Russia to develop distance learning courses that could be delivered via the Internet, a computer network, or via CD-ROM. An additional requirement was that the materials be convertible to HTML. PowerPoint was chosen because it was available to the grant participants in both locations. It met the requirements for potential tools to: provide the required means of delivery, be available to the Russian instructors, be available in Russian language software, be easy to use, and have a relatively low learning curve.

The sample course, Small Business Marketing, was designed to be instructor paced, with the lectures and most of the supporting materials contained within the course on the CD-ROM. Some of the examples used were selected to fit the Russian culture and included case studies of businesses in Borovichi. The material on the CD- ROM was also designed to coordinate with an available Russian language textbook. The pluses and minuses of the software will be discussed along with course and template design and evaluation.

Contact with the course's instructor was designed to be flexible based on the accessibility, needs and abilities of the students. The course was designed for multiple means of delivery to meet student needs. The content was designed to allow for the possibility of delivery via multiple channels including the Internet, computer networks, CD-ROM, and print.

Abstract: On-line learning is becoming more popular and realistic with the development of distributed network technology. However, the methods that take advantage of technology and integrate on-line learning into conventional classroom teaching remain controversial. Laboratory instructors evaluated an on-line anatomy lab course at the University of Calgary through questionnaires and direct interviews. Four lab instructors and one professor participated in this study. Results showed that to effectively integrate technology into the curriculum, it was perceived by the instructors as important to set clear teaching objectives, an appropriate amount and depth of information for the level of the students, and teaching strategies related to students' learning style and motivation. Laboratory instructors felt that the dynamic and interactive 3-D animation was motivating for students.

The Study

With the development of distributed internet technology, on-line learning is becoming more prevalent. However, the methods that can take advantage of the internet and integrate it with conventional classroom teaching remain controversial.

There are potential benefits of the Internet for teaching students. The Web:

- is a flexible, dynamic learning environment (Hackbarth, 1997; Ross, 2000)
- allows for multimedia presentations (Palloff & Pratt, 1999; Ross, 2000)
- provides students with access to a potentially rich, collaborative, and powerful learning environment (McGreal, 1997; Ross, 2000).

Kulik's (1994) meta-analysis of the findings of 97 studies on effectiveness of computer-based instructions concluded that students usually learn more in classes that received computer-based instructions, especially in elementary and high school.

However, there are many reports of ineffective distance on-line learning programs (Horton, 1999). Technological possibilities do not automatically transfer into effective teaching and learning (Loveless, 1996; Zhao, 1999). Designing and delivering instruction on the web requires thoughtful analysis and investigation of how to use the Web's potential in concert with instructional design principles (Ritchie & Hoffman, 1997).

There does not appear to be a consensus about the best method to evaluate on-line learning. Traditional evaluation models have concentrated on the empirical and quantitative procedures (Stufflebeam & Shinkfield, 1985; Worthen & Sanders, 1987; Simonsen, 1997). More recently, evaluators of distance education programs have begun to propose qualitative models incorporated with naturalistic methodologies frommore holistic perspectives.

Therefore, a qualitative study of the on-line anatomy lab course in the University of Calgary was conducted from the perspective of instructional design and teaching strategy. The on-line anatomy lab course, which was incorporated into the Kinesiology curriculum, was designed to offer students a wide range of learning media to supplement their study. The website of the program is: www.kin.ucalgary.ca/anatomy.

The on-line computer lab includes four labs (see figure 1). Lab I is an introduction to the computer lab and includes procedures for using this material. Labs II, III, and IV follow the same five-part format (see figure 2): introduction, surface anatomy, dissection, movement and testing. The dissection part is a completely separate program that has been incorporated into the Lab designed specifically for Kinesiology students.

Methods

Participants

Four lab instructors fromthe on-line lab course participated in this study.

Instruments and its validity

A five-point Likert scale and ten interview questions were used. The five-point Likert scale is based on Ross' study where he used compared conventional teaching and on-line teaching (Ross, 2000). Some of the interview questions are selected from the reviewed literature and the study of the Integrated Learning system (ILS) in an Alberta middle school conducted by M. Jacobsen (1996). The interview questions were presented under the following four sections:

- demographic information
- comparison with the conventional cadaver laboratory teaching
- students' interaction with other students and lab instructor
- teaching strategies

Procedure

After completing an informed consent form, participants were asked to answer a questionnaire on a five-point Likert scale and then interviewed. All interviews were recorded anonymously on tape.

Analysis of the results

A descriptive statistical analysis was performed on the questionnaires. The interview recordings were transcribed and cross-referenced for both common and unique responses.

Conclusion

Computer technology has provided many new educational possibilities such as distance accessibility, and interactive, dynamic multimedia learning environments. Effective use of educational

BEST COPY AVAILABLE

technology should take into consideration numerous elements. Results of this study highlight the need for instructional design, content, and teaching strategies that take into consideration learner characteristics as well as the classroom environment.

In this study, according to the lab instructors, the 3D animation and interactivity of web-based labs appear to have attracted student attention. Moreover, they suggested that the following factors be taken into consideration in order to develop World Wide Web tools to support classroom activities:

- course content should be current and relevant to learner needs
- expected learning outcomes must be clearly described
- too much text on one page should be avoided
- students should not be overwhelmed with information
- increased access to the Internet, and voluntary lab assignments should be encouraged.

Future study of student work-load and its impact on knowledge mastery, and student comfort with using technology as it relates to performance and attitude, is recommended.

Using Technology to Aid in the Creation of High-Quality Corporate E-Learning

David A. Guralnick, Ph.D.
Kaleidoscope Learning
386 Park Avenue South
Suite 1900
New York, NY 10016
dguralnick@kaleidolearning.com

Abstract: E-learning has the potential to make a huge impact on the corporate learning field,, but this potential has not yet been realized. In theory, e-learning can provide high-quality, individualized, easily accessible, on-demand, interactive learning and performance support. But in practice, most attempts to migrate to an online learning model have resulted in poor, inefficient training. I suggest that the primary reason for e-learning's failure to this point lies in the focus on technology rather than on learning. In this paper I propose a three-part plan to employ technology differently, with the end result being a focus on high-quality learning.

1. Introduction

E-learning has the potential to make a huge impact on the corporate learning field, but this potential has not yet been realized. In theory, e-learning can provide high-quality, individualized, easily accessible, on-demand, interactive learning and performance support. But in practice, most attempts to migrate to an online learning model have resulted in poor, inefficient training. I suggest that the primary reason for e-learning's failure to this point lies in the focus on technology rather than on learning. This has resulted in the following specific problems:

- People who are skilled in learning theory are often less involved, or not involved, in creating training; rather, the role of computer programmers and graphic artists is increased
- Technical structures often are allowed dictate the design of an e-learning piece, rather than the other way around
- Lack of software tools for trainers—most authoring tools are "pseudo-programming" tools which still require the user to think in terms of programming logic rather than focusing on pedagogy.
- The Web and corporate intranets are typically viewed simply as information repositories, thus failing to take advantage of what technology can offer: personalized, interactive, just-in-time training and performance support
- Technical implementation details take time, preventing trainers from focusing on content and pedagogy.

2. Technology and Pedagogy: Must They Be at Odds with One Another?

There often seems to be a war of sorts between the technology side and the learning side. I suggest here that this conflict is to a large degree unavoidable: there's a huge communication gap between the groups, and there is no easy way around it. These groups have different skills and essentially speak different languages, and their design and development styles often are at odds by their very nature. While an admirable attempt at finding a middle ground, today's authoring tools are "pseudo-programming" tools, designed to let people build Web sites and programs without actually programming—but in practice that means "without writing actual code," rather than "without thinking in terms of programming logic and technical details"; the users of such tools do need to create programming logic even if they do not need to know programming language syntax. Given this difficult situation along with the temptation to garner the benefits of e-learning, many trainers today are trying to "catch up" by following one or more of several plans:

- Outsourcing their e-learning projects
- Hiring a programmer or programming team to help them

- Learning to use authoring tools, which themselves generally fall into two categories: those with a steep learning curve and a programming-like feel; and those which are simple to use but create only very simplistic products with little likelihood of teaching effectively.

The first option, outsourcing, is expensive, and over time also becomes inefficient if the vendor needs to be involved in the updating process as well. The second option, a programmer or programming team, is also quite costly, and it is very difficult to create a good quality product with such a project team; the technical details end up dictating the learning rather than the other way around. The third option, authoring tools, provides trainers with the greatest control over the learning experience; yet the amount of work required is substantial, and much of the work is necessarily focused on technical rather than learning issues. The learning design part is already difficult to do well, and while it is the trainers' core area of expertise, if they spend their time handling technical issues, their skills are going to waste. Imagine if a trainer wanted to produce a print manual and needed to understand how a printing press worked—building training with today's authoring tools can seem just as nonsensical.

What can we do about this problem in order to allow quality e-learning on a large scale? In this paper I propose a three-pronged method to creating effective e-learning on a large scale, and describe some elements of this approach. The three components are:

- "Learning Architectures": technology designed specifically to support good training
- A technical engine, invisible to the users, to support personalization and customization
- An e-learning creation "control center," with authoring methods that are intuitive to trainers, and support tools to help trainers organize and understand their content.

In the following section, I describe this new method in more detail, and draw from real-life examples of works that are either in the prototype stage or have already been deployed.

3. The Approach

3.1 Learning Architectures

Sound learning architectures that make use of the interactive capabilities of the medium are key to creating successful e-learning. In many ways, this is the next logical step in the development of online learning; whenever a new technology is introduced, its first uses closely resemble products designed for old technologies, which fail to make use of the new capabilities. Elearning has remained in that stage for too long. The idea here is to create learning architectures, beyond online manuals or Flash animations. These architectures are built around the learners' goals and, while good training design and good content are also necessary (and the responsibility, as well as the core skill set of the trainer), the architectures provide conceptual building blocks for sound training. Examples of learning architectures include:

Procedural learn-by-doing simulations

- **Goals**: Learn by practicing a real-life task.
- **Description:** The learner is given realistic scenarios and a simulated environment, and must work through them. A teaching component provides guidance and feedback, as a real-life coach would.
- **Uses**: This architecture is best for procedural tasks where there's some notion of a recommended way or ways to do things—examples include operating software or equipment and script-based soft skills such as many customer service jobs.
- **Sample Training Applications:**
  - **Laser Radio Terminal (LRT) Training**: Retail employees use handheld LRT scanners to track store inventory and locate product. The LRT terminals run a set of software applications, and mistakes made by employees can have drastic consequences on the accuracy of the data. The LRT Training simulations present users with real-life tasks in which they must perform actions with LRT software, using a simulated LRT on their computer screen.
  - **Guest Service Video-based Simulation**: Here, retail employees learn about customer service skills and store policies and procedures, by handling customers who appear in video, with realistic consequences played out for each action.

Rate-and-Review training activities

- **Goals**: Learn by observing the performance of a task, reflecting, and discussing it with others.
- **Description**: Users watch a task being performed by someone, generally through video or audio, ad rate the performance along several dimensions, and compare their thoughts with those of peers and experts.
- **Uses**: This is best for tasks which are visual, and/or expensive or difficult to simulate, such as coaching employees, where body language and personal style weigh heavily.
- **Sample Training Applications:**
  - **Coaching Training**: Retail employees watch videos of coaching situations based on real-life problems that they may face in their own jobs. They rate the video coach along several dimensions, then compare their ratings with the way their peers and some experts viewed it. They then can read explanations and see the same situation handled in a better way.
  - **Crisis Training**: Corporate employees watch a crisis situation unfold in video, and see how the company handled the crisis. Again, they rate the quality of the response, and can discuss with peers and experts. The learning goals here are for the users to become more proficient in handling crises.

Solid learning architectures in conjunction with a good trainer can produce excellent e-learning end-products. But the end-product itself is only a piece of the overall puzzle. If we want a way to produce quality e-learning on a large scale, two other areas must be addressed.

3.2 The Technical Engine

The goals of this technology piece are to support customization and personalization—so that content can be reused but in a way that always feels relevant to the user and the situation. For example, suppose a retail chain wants to teach their supervisory employees how to coach their staff. The audience however, is made up of employees with very diverse responsibilities and skills.

Generic coaching tips and instructions will not work - learners are notorious for deciding quickly "that doesn't apply to me." On the other hand, it is ridiculous to expect the trainer to create several entire coaching pieces from the ground up, such as "Coaching Cashiers," "Coaching Unloaders," and "Coaching Food Service Employees."

The basic underlying structure of the technology must allow the trainer to include both general information (in this example, coaching principles such as "coach positively as well as negatively," or "give feedback in private") and position-specific information that makes the training relevant to each different audience. Then, the technology must integrate the two seamlessly when the site is accessed so the end-user, for example, the cashier supervisor, doesn't notice or have to wade through information and examples relevant to the unloading supervisor.

In addition, learners need to be able to quickly and easily find the information, training, or other on-the-job support they need, which requires a good search engine, sound indexing of the content (as opposed to a plain text search which pulls up far too many results to be useful), and a clean interface for the end-user.

Up through this section, with a technical implementation adhering to the above guidelines, we now have the ability to have good training for a large group, including efficient content reuse, when they need it, in a personalized and customized way.

3.3 The Trainer's Control Center

In order for this approach to work, trainers need to be able to actually employ it—on their own, without programmers or outsourcing vendors. This means that they should be able to build e-learning while using minimal technical skills, and also maintain, study, organize, and customize the training and content. A software tool for trainers to do these things requires a focus on content and training rather than a focus on technical structures. The technical structures in section 3.2, along with the learning architectures in section 3.1, combine to form the underlying basis for this approach, but the training development platform itself should support a trainer in the following ways:

- It must have a natural, intuitive interface
- It should use a vocabulary of training and content, not of the technical world—for example, trainers can build "simulated tasks" rather than "branching models".
- It must offer support tools to make the trainer's development process simple and error-free. These tools come in two varieties:
    1. Basic quality assurance, such as spellcheck.
    2. Complex, content-centered tools, such as detailed reports describing the content of a training site.

The Control Center toolkit is currently a work-in-progress and will be completed in December, 2002. For the future, the next generation of these tools can include features that support the learning design process by training the trainers to design better online learning environments.

4. Conclusion

Technology and pedagogy can indeed coexist, and can join forces to create the e-learning that has been long discussed. In order to reach this point, we need to make changes in the way the two fields view each other and work together. Only then can large scale e-learning truly have an impact. Under the plan described here, trainers would still need to become expert at some new skills in order to create training under new, more-complex learning architectures. But these are natural evolutions of the trainer's current skill set. Technology, under this plan, plays a background role and supports and assists in the creation of sound learning, available just-in-time to end-users. With such a learning-focused plan, the true potential of e-learning can be realized on a large scale.

ESTABLISHING A PEDAGOGICAL PLATFORM FOR DELIVERING POST GRADUATE EDUCATION AS BLENDED E-LEARNING.

Author: Andrew Hall
Institution: University of Manchester, School of Nursing, UK
Email : andrew.g.hall@man.ac.uk

Abstract: This paper focuses on the implementation of a blended e-learning resource-based learning and tutoring approach for post graduate study and the implications of this for on-campus and off-campus students. In particular the paper address issues of appropriate pedagogy and the use of new media to expand and improve on the traditional lecture based approach.

The project

The conversion of traditional Masters level modules in research methodology for health professionals, which form a key unit of study for postgraduate students, too distributed learning materials for flexible off or on campus delivery. The project has made extensive use of streaming media and use of a VLE. During the project each aspect of teaching and learning has been explored, the pedagogy questioned and the content examined. The process has been of benefit to both staff and students in relation to the nature and content of the learning materials.

Traditionally each unit was delivered through a series of six lectures or teaching sessions over a period of six weeks. After review and development each unit is now a half module and can standalone or be integrated into other study packages and is delivered as blended e-learning over one semester. The core learning material is available on the web; students access this and then undertake individual & group activities, face to face if on-campus, by use of asynchronous web based communication if on-line. After each block of study, students present a review of their work in academic seminars if on-campus or online if not. Assessment is by a summative assignment supported by a portfolio of selected coursework with reflective statements.

The pedagogy

For Candy (1991) self direction is a process where learners gradually take control of their learning as well as an environment that encourages travel towards an ideal end point of self direction. During the development of materials it be came clear that this is a multi layer model with each layer built on a similar principles; the programme of study was designed to encourage the students to be more independent at the end than at the beginning Caffarella (1993), as was each module and each learning session. The structure of the learning material, the nature and content of the resources, wording and nature of the tasks all encourage the development of inquiring and analytical study and the exploration of other related routes of investigation with the assumption that the independence of the learner would grow. Knowles (1980) provides criteria that can be used to judge the value of the learning material in reach this end. In particular do the learning materials promote the ability to formulate questions that are answerable through inquiry and to generalize, apply and communicate the answers to question raised.

Tennant (1997) identifies assumptions within the humanistic concepts of self-development and self-direction, which, he argues, the evidence base does not fully support. The project team had some sympathy for Tennant's argument that there is inherent in the assumption of *self-directed*, a contextualization of the self that is often not addressed in these debates. By placing the self-directed elements of study after more structured elements context could be provided by the expertises that lie within the knowledge and work of the content experts, not in a traditional didactic fashion but through the shaping of tailored learning. As such the self enters a world where initially the context of study is apparent. The student is therefore expected to develop at multiply levels: as a subject expert; as a learner; and as a professional within a given context. The development of open ended linear routes, which draw on the knowledge and experience of the subject expert, guide learners through a pattern of predetermined resources and activities, promote both subject focused learning and the skills of the independent learner, and lead to more open explorative study, provide a framework for such an approach.

Weil & McGill (1996) argue that the experience of the learner has value and that learning should be active, meaningful and relevant to the agendas of the learners; Laurillard (1998) identifies a conversation framework as key to the development of a critical perspective, necessary for academic understanding. These principles were employed in the structure of the learning materials and assessment. At each key stage students are presented with a number of resources and an activity that is undertaken in two parts. The first allows for consideration and reflection on the requirements & resources and the second requires students to engage with tutor and peer group to consider the contributions made. Within this facilitated dialogue, learning is an active process in the construction of meaning with the experiences and knowledge of the student cohort contributing to knowledge base of the group and its understanding of the issues under investigation. The method rewards collaboration and this is enforced by part of the assessment process being linked to the outcomes of the discussion. The ability to be responsive in this element allows the tutor to develop themes that the students have identified as of particular interest and if so desired to communicate these to the wider group. Additionally at this stage the tutor can facilitate the students learning to learn Wallace (1996), how to learn and direct themselves through information, concepts and tasks. Activities are built around problem solving, knowledge sharing, the construction of an analytical approach and the production of knowledge and as such work focuses on what Salmon (2001) identified as stage 4 skills.

New Media

Much work has been done on the potential of low bandwidth streaming media both video and audio in production of learning resources. A key benefit of which has been the potential for personalisation of the learning programme. Resources can be produced that address the needs and interests of different cohorts of students within the same pedagogical framework. Students of Nursing, Public Health, Socialwork, Medicine and others can view case studies and new media resources particular to their field and then engage with learning materials that draw on areas common to research methodology. This form of personalization would not be possible in a traditional setting and together with the acknowledged advantages of web based delivery in relation to accessibility, provides a strong driver for such development.

Conclusions

Through the development of this project we hope to address the major current pedagogical themes in the delivery of education through new media. In particular we hope to have established an adaptive educational framework which can support and influence the delivery of other post graduate programmes and programmes at other levels of study. We have drawn on elements of different theoretical approaches to develop a methodology that we feel is appropriate to the students in our institution and that may have generalisable outcomes. The course runs live in Sept 2002; we have obtained funding for a two-year research project into the educational experiences of different student cohorts.

Abstract: This paper describes a model for design of web-based learning system which is guided by two fundamental, and somewhat contrasting, design themes: problem-based interactivity; and progressive scaffolding. It is proposed that effective systems should be built around core problems, which require the active engagement of the learner. It is also proposed that the learner should be provided with scaffolding to support problem solution in a progressive manner going from the most general and minimal guidance to the most specific and detailed. It is then up to the learner to select the tool at the necessary level for problem solution. A prototype system for teaching web design, which was designed to examine the two fundamental components of this approach, and on-going usability testing of the prototype are also discussed.

Introduction

Although the number of web-based learning systems that have been developed in recent years to support distance and face-to-face classes has grown exponentially in recent years, research indicates that much of the promise of these learning systems has not been realized (Reeves, 2002). There are a number of reasons for this. A primary reason is that little thought or effort goes into design and research before the tools are implemented (Hall, Watkins & Ercal, 2000, April). A fundamental characteristic of effective learning environments is that they promote and encourage active learning; and many web-based distance courses, and even elaborate multimedia simulations are simply used to display information, without requiring students to interact with them. At the same time, research in hypermedia learning systems indicates that it is also very important to provide a learner with some level of guidance(Shin, Schallert & Savenye, 1994), and this too, is often lacking in these web-based systems. Finally, the ineffectiveness of these tools is almost surely partly due to the lack of research on these web-based learning technologies (Dillon & Gabbard, 1998). The vast majority of web-based courses and modules have not been pilot tested or evaluated prior to their introduction into the curriculum.

Computer based learning systems and the World Wide Web afford us an opportunity to move education to a new level, both to enrich traditional instruction and to provide instruction at a distance. However, such a transformation can only be realized through the application of systematic principles of instructional media design and through close interaction between content providers and web designers (Hall, Feltrop & Davis, 2001, April).

The purpose of this paper is to: a) Introduce a model for such a Web-Based learning system; b) Describe an example of such a system for teaching Web Design and Development currently under development; and c) Describe an initial usability study currently in progress.

Problem-Based Progressive -Scaffolding

The system currently under development is guided by two fundamental, and somewhat contrasting, design themes: problem-based interactivity; and progressive scaffolding.

At the core of each module is a problem, which requires that the learner actively integrate knowledge from multiple sources and apply basic methods and procedures for its solution. A large body of educational research indicates that learners learn most effectively when they are activity engaged in learning, as opposed to passively reading or listening (Brooks, 1997). Further, problem solving is at the core of meaningful learning.

"Progressive scaffolding" is the term we use to refer to a systematic method of providing learners with and optimal level of guidance(Hall, Watkins & Eller, in press). The system is designed in such a way that supporting materials are offered in a progressive fashion, from the most general and minimal guidance to the most specific and detailed. It is then up to the learner to select the tool at the necessary level for problem solution.

A Prototype System

We are currently developing a series of learning modules based on the system described above for teaching Web Design and Development. The system is intended to support a face-to-face class at the University of Missouri-Rolla on this topic, but it is also intended to be appropriate as a component of a distance learning class.

To begin development of such a system, we first created a prototype module, which is a step-by-step description for how to create a fairly elaborate web page, using the web development tool *Dreamweaver©*. To create the page, the user must apply a number of general procedures including: setting up a site; adding tables & graphics; using tables for page layout; inserting text; creating hyperlinks; creating image rollovers; and creating a disjoint swap image behavior.

This initial system is straightforward and is intended to examine the key components of the model above, so the initial interface is very straightforward in design. The progressive scaffolding is provided in the form of different levels of information for displaying each step in the development process: a) Text; b) Graphics; c) Narrated Video. A screen shot from this prototype system, which is currently under examination is displayed in Figure 1.

Usability Testing

This system is currently undergoing usability testing with students in General Psychology classes at the University of Missouri-Rolla serving as participants. Each student works with the system for forty-five minutes with the specific goal of recreating a model web page that includes all of the components cited above. Each participant's session is recorded including dynamic screen video capture, user facial expressions and audio; using a typical usability testing scenario (Dumas & Redish, 1999).

The principles questions that are being examined in the analysis of these session recordings are:

1. To what degree were students successful in creating the page using this prototype interface?
2. To what degree did students utilize each of the progressively complex types of guidance (text, graphics, and video)?
3. What is the relationship between 1 and 2?

Of course, any other trends or themes that emerge with regard to participants' traversal through the stages of the task and it's relationship to performance are also being noted, and, most importantly, recommendations for the continued development of the Web-Based learning system are being delineated.

Abstract: In this paper, we describe the design and multidisciplinary evaluation of a new university course for teaching complex topics in probability and statistics. The course combines traditional third-level instructional elements, lectures and tutorials with interactive Internet instruction[1] and quick response e-mail support for students' urgent queries. The design of interaction for the course marks a return to *education as usual*, and a turn from the *Big education* (Stevens, 2002), *business as usual* approach to learning. *Big education* is concerned with using ICT[2] to automate education, premised on the simplistic assumption that learning is simple. This new math course was designed however on the basis that learning is complex and that effective use of ICT in higher education necessitates going beyond simply posting lecture slides to the Web, and furthermore that effective teaching can be supplemented, but not substituted by ICT. In addition, the new course was designed with the intention of preserving and enhancing traditional, but effective aspects of the course pedagogy. However, the new course is at the same time not quite a return to *education as usual* in the sense that its designers wanted with this new course to create a complementary combination of ICT support and offline interaction to try to overcome some limitations traditionally faced in trying to teach the course's complex subject matter to a very large group of students. In evaluating the new course we adopted a multidisciplinary approach, drawing for our critique of the new course on three different perspectives: collaborative learning and work, HCI/usability analysis and instructional design. We document how adopting this particular, 'tripartite' approach helped us to gain some significant perspective on the complex design and delivery of the course. We document also how this approach has enabled us to envision possible improvements to instructional and organisational aspects of the new course.

Introduction – Big education, big possibilities

> *This has become an era of intense efforts around standards, accountability, and socially consequential tests for the masses. It has become an era of aspiring technology millionaires for whom education is an enormous open market. In short, it has become an era of Big education.*
>
> (Stevens, 2002:269-270)

In the age of *Big education*, there are big possibilities. But we need to ensure these possibilities are big for learning. ICT, the Internet and related technologies promise much for education but their real value is to be found, not in determining how they can be used to replace teaching, but how, in combination with more effective teaching and more effective conditions for learning, (within and without the school), these technologies can serve as valuable adjuncts to learning.

> *The Internet is just one component of a new socio-technical system with great learning potential. Just as it matters which books students read, it matters which Internet software*

> *they use. And it matters what activities and social practices surround the process of Internet use in schools and at home.*
>
> (Bruckman, 2002:60)

The designers of the new mathematics course aimed to use ICT in concert with more effective teaching to create better conditions for student learning. They also intended "not to use the new media to do the old thing" (Papert, 2001) but to use ICT in combination with face-to-face and other ancillary student support to overcome some of the difficulties of teaching complex mathematics topics to a very large class.

Description of new mathematics course

197 undergraduate students take the MA4704 course in the spring term, each academic year. The course is a required credits course for the students, who all study in cognate disciplines: computer science, engineering and applied mathematics. The course is for many students their first experience of statistics; the presumed knowledge for the course is second-level or K-12 mathematics. Some of the students will previously have studied statistics in other courses or colleges. A multidisciplinary team developed the interactive instructional Web site for the new course. The team-members came from a range of backgrounds, including graphic design, biology, multimedia, computing, science teaching, and computer-based training. The team was composed of an instructional designer; two graphic designers; a software engineer; a Web specialist; a project manager; a content quality assurance lead; one teaching assistant; one tutor; and the lecturer. The Web site for the new course took approximately 9 months to design and implement. Students normally access the site from computer labs in the university; they can also access the site from home. Tutorial sessions are run twice weekly for students and in these they work through problem sheets related both to content in the lectures and to topics on the Web site. If students are experiencing particular difficulties with course topics, they can use the Dr. Dr. e-mail support: they can e-mail a query to the course TA and she will reply within 24 hours. Students can also attend additional help sessions in the Maths Learning Centre, located in the Mathematics and Statistics Department, where they can receive further, one-to-one or small-group tutorial assistance.

Our multidisciplinary approach to evaluation

For our evaluation of the course, we took elements from three disciplinary perspectives, from collaborative learning and work, HCI/usability analysis and instructional design. We had three concerns: (1) to assess the instructional effectiveness and usability of the course tool, the interactive Web site; and (2) to get some sense of the overall pedagogical efficacy of the novel course. And, in addition to our interest in the collaborative work of students, we were also interested in the collaborative work practices of the course designers and teachers, (3) with a view to generating some insights into how these practices might be better supported.

Usability analysis and evaluation of instructional design

We applied the Thinking Aloud protocol in assessing the usability of the Web site. For this part of the evaluation, we asked three students to follow the protocol as they completed a new topic on the Web site. We used an online questionnaire (http://richie.idc.ul.ie/tony/questionnaire_ma4704.html) to supplement the feedback we received from the Thinking Aloud evaluation with the small sample of students – we intended to garner some specific results with feedback from the class group in general about instructional and usability aspects of the site. We also held short semi-structured interviews with the three students to get their reflections more generally on the course and its instructional approach. 101 of the 197 students responded to the online questionnaire. In assessing the instructional design of the course Web site, we drew on aspects of Merrill's (2002) First Principles for Effective Instruction, including, for example: is the courseware presented in the context of real world problems? And, are there techniques provided, which encourage learners to integrate new knowledge or skill(s) into their everyday life?

Getting through the 'Net

We found in our evaluation that students can get through the topics online without really having to think critically about them. Asked about the Web site, one of the interviewees said: "more searching questions need to be asked". Examples are the self-tests on the site, which loop continuously until the student gives the right answer. A number of the students we interviewed said that in the self-tests they often just kept trying different answers until they 'got the right one', without reflecting on why it was the right answer. The self-tests also create the fundamental usability problem that the user no longer has control - if a wrong answer is proffered the navigation buttons disappear. And there is also the pedagogical issue that this having to keep doing something until you give the right answer is too traditionally pedantic. One of the interviewees commented: "It's like school, being forced to give the right answer." Of the online animations and the course generally, the students in the interviews and questionnaires reported that they found this a much more interesting and meaningful way to teach statistics. One student remarked: "This is a much better and more interesting way of teaching prob and stats than normal lectures which can be very tedious." However, while students said the new course certainly gave them much more of a sense of how statistics can be applied in the real world, which should help them to integrate their new knowledge of statistics concepts and principles into their future internship or professional work, we found from the interviews, questionnaire and Thinking Aloud evaluations with students that there is perhaps too little *synthetic* interactivity available for students on the Web site. There is not enough, it seems, of a challenge and opportunity for students to actually do (*synthesise*) statistical work and reflect critically on it. To illustrate the use of instructional technology to facilitate creative or *synthetic* interactivity, and to help elicit critical thinking, Merrill (2002) gives the example of courseware that involves the learner in using MS Excel to prepare previous month's sales figures for a friend's shop. The instructional technology facilitates the learner in working through a real world problem. The courseware replicates Excel and the learner creates the workbook; enters the data; and creates the calculations and finally the financial report. In using the instructional technology, the learner is necessarily required to focus and reflect on spreadsheet concepts. The courseware also supports instruction with *non-examples*, which means the learner can make mistakes or take a problematic path through the scenario but she receives feedback on where she is going wrong. Another problem we found from our interviews concerned students' submission of answer sheets over the Web. The response page only informed students their data had been submitted without telling them what they had submitted. Furthermore, when they got back their results, they were just told their mark, and they were not told what they had gotten right or wrong nor why they had gotten certain things right or wrong. We would argue that the instructional design for the course Web site, while generally very good in aesthetic terms and in terms of usability and clarity of explanations, could be changed to better support critical thinking about statistics. In general, instructional artefacts should be designed to facilitate the development of learners' critical aspect and inquiry skills by supporting them in asking the right kinds of questions, and not with giving right answers *per se* (Koschmann, 2002; Hall & Wright, 2002). This change in the site design would need to be complemented with changes in the way feedback is provided on the Web site - students would need to receive feedback as they work through topics, and not just feedback on what they are getting right or wrong, but moreover why they are getting things right or wrong.

Online collaboration - beyond the *electronic soapbox*?

One of the problems we found with the course is the lack of support, ICT or other, for collaboration among students. We argue that online collaboration could be useful pedagogically, particularly for those students who access the course Web site off-campus, to give them some support where peers or tutors are not physically accessible for ideas or to take questions. Some online collaboration, like computer programming developer fora on the Web (for example, see http://forums.internet.com/), where students can post questions and post answers and solutions to problems, and where they can see how other students are approaching problems related to course topics. This online collaboration would be used to complement the critical aspect and real world focus of students' interaction on the Web site. This forum would require moderation but a Netiquette for the forum could be developed so that students use it appropriately. A chat room or unstructured e-mail discussion might not be that useful as we have found these can deteriorate into *electronic soapboxes* – that is students log on and contribute various unrelated comments that lack cohesive or logical threading. Also an online forum could be useful in further grounding statistics for students and in relating it to real world applications by using the Web to link students to practising statisticians in the workplace. It could be used to involve professional mathematicians and statisticians in discussions and in helping students to work through real world statistical scenarios on the Web site. This *community of practice* approach has previously been tried with some promise in teaching Computer Support for Co-operative Work (CSCW) (Eales et al, 2002). Our evaluation also revealed that there is a need to consider again in general how the Web site content sits with the lecture material. One of the students commented: "very useful but all of the information should be on it [Web site] instead of being at 1 level on the web and another in the lectures this was very confusing." In terms of helping students pace their own learning, overall the course has proven very successful As one student noted: "I found this method very interesting, I could work through it at my own pace and attempt questions before looking at the answers. I could also take detailed notes at my own pace."

Conclusion

The design and delivery of the new MA4704 course marked a turn from *Big education* and the simplistic principle that learning is simple. The new math course was designed on the premise that learning is complex In this paper, we have attempted to illustrate how a particular multidisciplinary approach to evaluation of this new course helped both to highlight problematic aspects of the course's design and delivery, and to provide insight to possible ways to improve these. Notwithstanding, subsequent research is warranted to investigate how this specific evaluative approach might be enhanced through meaningful combination with other disciplinary perspectives, or elements from. The combined approach we adopted worked well in helping to assess and uncover possibilities for the design of interaction and ICT in the context of a university math course. But different educational settings are likely to require different combinatorial or multidisciplinary approaches to evaluation, appropriate for the respective contexts of learning.

An Assessment of Synchronous Online Audio Conferencing for English Language Instruction

Sandy McIntosh
English Language Program, Faculty of Extension
University of Alberta
Canada

Abstract: This paper is a report on the findings obtained from a pilot study using a synchronous online audio conferencing tool (CentraOne) for English as a Second Language (ESL) instruction. The study examined the responses of ESL students towards the use of this medium for the purposes of discussion. Students' responses varied, but overall they were positive; they seemed to feel quite comfortable with the tool and enjoyed the discussion, especially when they were broken up into smaller groups. However, many of the students found that inconsistent volume levels and lack of non-verbal cues, hindered communication.

Introduction

The Faculty of Extension's English Language Program (ELP) endeavors to deliver effective distance courses for ESL instruction that include the traditional four language skill areas in online course design: reading, writing, speaking and listening, as well a consideration for academic critical-thinking skills. The existing text-based resources do not meet the requirements for speaking and listening when incorporated into online instruction. While a number of synchronous instructional tools offer multi-point audio conferencing, it is not yet known how well these products work in the instruction of ESL or whether they offer an adequate replacement for existing face-to-face instructional methods. To better understand the strengths and weaknesses of these types of products for online ESL instruction, as well as the appropriate instructional methods for their use, it is necessary to perform careful evaluation of these tools. A pilot study was conducted as an initial step in this evaluation process; it provided a realistic pedagogical context for the evaluation of a multi-point synchronous online audio conferencing tool.

Review of relevant literature

Numerous studies deal with the more general issue of computer and Internet mediated communication for education (Gibson & Herrera, 1999; Seagren & Stick, 1999). At the present time, new elements of technology and pedagogical design continue to emerge in language education, resulting in varied program configurations. This inconsistency in design is reflected in Salaberry's (2000) report on a project to determine best practices in computer-mediated communication, specifically for second language learning.

The pilot test in question focused specifically on synchronous, online audio conferencing with both instructor-directed and peer-to-peer activities. Recent studies have examined the effects of synchronous video and audio-based online learning environments (Voice-over-Internet Protocol). In a study of synchronous online instruction with one-way video and two-way audio, Hofmann (2000) observed that the technologies became transparent in the learning process, and content, rather than the medium, became the focus. According to Appelt and Mambrey (1999), synchronous virtual learning environments seemed to increase the quantity and quality of student-to-student and student-to-instructor interaction, subsequently establishing a network of communication and collaboration among participants.

Overview of the Project

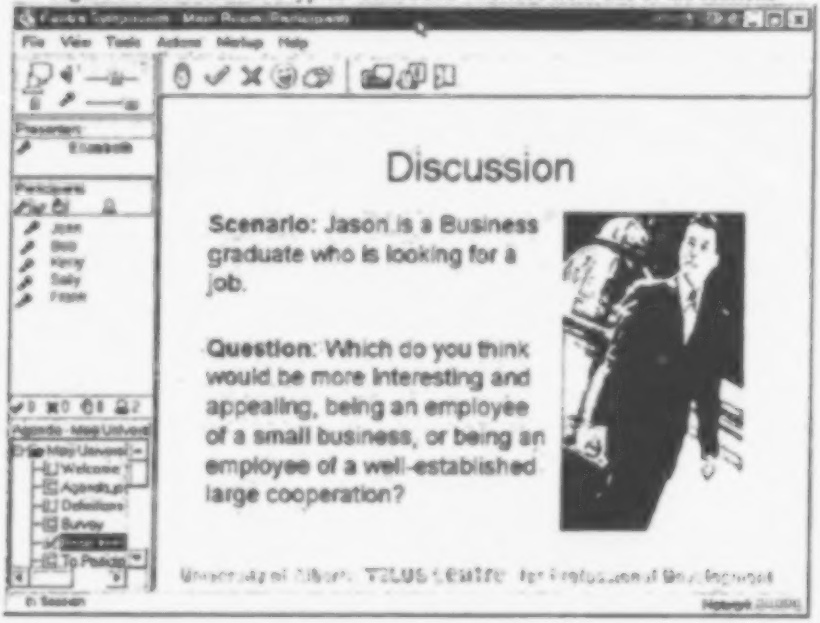
The TELUS Center for Professional Development was responsible for the planning and delivery of a pilot project comprising four (4) synchronous online sessions using CentraOne. These sessions were used to supplement the speaking and listening portion of an English as a Second Language course (Business English), at the Faculty of Extension. Participants were international students, mostly in their early 20s, whose ESL proficiency was rated as "advanced." The Business English course was designed as a terminal course, for students who intend to use English in their professional work.

Other participants in the sessions were: a CentraOne facilitator, the project coordinator, and the ESL instructor for Business English. The facilitator was a specialist in Educational technology and offered assistance in both the technological and pedagogical aspects of the project. The project coordinator was a specialist in program development for post-secondary education. The instructor, a specialist in classroom based ESL, provided the students with 20 hours per week of ESL instruction, including one hour per week in the pilot sessions. Apart from the pilot sessions, all ESL instruction for Business English were classroom based.

CentraOne is a web-enabled learning and collaboration environment using Voice-over-Internet Protocol (VoIP) software tool for synchronous conferencing (See Figure 1). Only some of the capabilities of CentraOne were utilized for the project. Specifically the following tools were utilized: audio, chat, whiteboarding and graphical slides, break out rooms, surveys, and evaluation. In the sessions, each participant was assigned a computer with headphones and a microphone, which could be used to speak to the group through the online medium, with permission from the facilitator. Only one participant could speak at a time, but all other participants could hear the speaker. In addition to audio conferencing, participants could communicate freely and synchronously with brief written messages and could also take part in simple communication such as voting or requesting permission to address the group by clicking on various icons.

Each synchronous online session was approximately one hour in duration. An average of 15 students participated in each online session. The first session, which took place near the end of March 2002, consisted of orientation instruction in the use of the tools and a brief discussion session. The remaining sessions occurred once per week during the month of April 2002. The course instructor, students, and facilitator actively participated in these sessions.

Figure 1: Screenshot of a typical CentraOne interface from one of the sessions



Discussion

Scenario: Jason is a Business graduate who is looking for a job.

Question: Which do you think would be more interesting and appealing, being an employee of a small business, or being an employee of a well-established large cooperation?

Overview of the Process

The project consisted of two main phases: 1) Planning, 2) Delivery, and 3) Evaluation.

During the planning phase the facilitator set up the synchronous online sessions. For each session, the facilitator created user accounts, created and managed events, and uploaded the agenda and content. The Business English instructor, in collaboration with the students, delivered the content for the sessions verbally or through documents e-mailed to the facilitator. The facilitator spent a maximum of two hours per session preparing the

BEST COPY AVAILABLE

content for synchronous online delivery, uploading the content and preparing the event. For the first session the instructor completed an orientation rehearsal with the facilitator to detect and resolve any potential problems, prior to the actual event, in addition to the instructor, to become comfortable with the technology.

During the delivery phase, the facilitator assisted the instructor and students in the delivery of the synchronous online sessions, giving the microphone to the students and instructor as appropriate. A brief orientation was provided to students at the beginning of the first two sessions. This was intended to familiarize them with the CentraOne tools and to make them feel comfortable with the unfamiliar computer based technology.

Aside from making observational notes of the proceedings, the project coordinator assisted students with start-up, as needed. Both the facilitator and the instructor monitored and participated in the discussions. The facilitator participated in the sessions online and was only accessible to the other participants through the medium of CentraOne. The instructor was physically accessible but participated solely online. The students worked in one computer facility, with the instructor and the project coordinator. The computer facility was designed with limited sight lines that discouraged physical interaction between participants, outside the medium of CentraOne, and interaction was minimal during the sessions.

The assessment process focused on student approval ratings and comments. As simplicity and immediacy were considered to be desirable characteristics of the process, students were given the evaluations as a closing activity for each session. Student responses to rating scales and comments regarding approval or disapproval of the virtual classroom software were recorded within the medium of CentralOne. Ratings and comments were collected throughout the entire project and aggregated over time for analysis. In addition to the collection of data from student surveys, the project coordinator, the facilitator, and the instructor recorded observation notes during each session for the duration of the project. An informal debriefing session for the observers was held at the conclusion of each instructional session. Observational data were compiled and recorded from the three observers, over the duration of the project.

Findings

The pilot study examined the reaction, attitude, and comfort level of ESL students in using a synchronous online audio conferencing tool for discussion purposes. Based on the feedback gathered from the students at the end of each session, the majority of students indicated that they enjoyed using this tool for the purposes of discussion and were comfortable enough with the technology to complete and participate in the sessions.

It was observed that the students' and instructor's levels of enthusiasm and apparent confidence around the technology increased with each session, over the duration of the project. Specifically the students appeared to enjoy the use of break out rooms for smaller group discussions, compared to having larger discussions as a class within the tool. They also found the technology appropriate for communication of ESL students at a distance. Some of the negative comments around the tool focused on the varied microphone levels and the lack of non-verbal cues, which made communication difficult at some points.

An interesting phenomenon was that the From "Session 1" to "Session 2", the "Very Comfortable" rating declined from 27% to 23% and the "Not Very Comfortable" rating increased from 0% to 23%. This may be attributed to variations in lesson formats between the two sessions, as students were asked to participate more actively in the second session than in the first one by being assigned the responsibility of leading parts of the discussion. While they seemed to enjoy being leaders and moderators of the discussions, students found this role quite challenging. By the end of the term satisfaction ratings had almost returned to the original levels, however 10% of the participants emerged to express strong dissatisfaction. By ESL standards, the quality of discourse improved weekly.

Recommendations for Designing and Delivering Synchronous Online Sessions

The following recommendations are based on synthesis and analysis of the data collected from the project:

1. Orientation lessons at the beginning of each may need to be extended across many sessions throughout the course, to ensure that they feel comfortable with the technology. Orientation should include checking microphone and headphone volume levels.
2. The instructor should be given personalized technical assistance throughout the project, as needed.
3. Students should be placed in "break-out rooms" to provide opportunities for discussion in small groups with three to five participants.
4. Students should be given opportunities to lead discussions in a way that empowers them to solicit increased participation from other students. Training for student discussion leaders may be beneficial.
5. Courses using multi-point audio conferencing tools should be scheduled over an extended period of time. This would allow participants to become comfortable and proficient with the delivery technology in the early stages of a course.
6. It is important to engage the instructor in a pilot project early in the planning process. The support and cooperation of the instructor are necessary for the success of a project.

Conclusion and Suggestions for Further Research

As a first step to integrating synchronous online conferencing into ESL instruction, attitudes and the comfort level of students were examined and evaluated. The results from the study were encouraging and useful. However, further research needs to be conducted to determine how well synchronous online audio conferencing tools work in ESL instruction. There are many issues that need to be addressed in further research on this tool; the following are suggestions for further research:

1. Determine if ESL students of a different age group and, with different proficiency levels would respond to the tool in the same manner.
2. Examine the responsiveness of ESL students using a synchronous online audio conferencing tool at a distance for a class/course.
3. Examine the achievement of students using a synchronous online audio conferencing tool over an extended period of time.

Web Access Evaluation and Repair Tools - Automation and Integration

Laurie Harrison
Adaptive Technology Resource Centre, University of Toronto

An increasing number of software utilities to support web accessibility are now appearing on the market, all claiming to automate the process of evaluating and/or repairing Web pages. These tools assist the author in identifying the changes needed in the HTML code in order for the pages in question to conform to standards to ensure access by people with disabilities. Recent developments in this market demand particular attention to two areas: 1) models for integration of evaluation and repair within the html authoring tool and 2) models for integration of authoring tool support within the courseware environment.

There are two sets of standards that are generally used by developers of these evaluation and repair products to set benchmarks for compliance. The first is the Web Content Accessibility Guidelines 1.0 from the Web Accessibility Initiative (WAI) of the World Wide Web Consortium (W3C).[i] and the Section 508 requirements, amended in 1998."[ii] While these two sets of standards provide the context for evaluation and repair, further attention must be paid to the role of authoring tools, such as HTML editors, in development of accessible resources. A grassroots approach including integration of accessible authoring practices and validation processes into the design phase would reduce the need for the evaluation and repair tools. However, as yet, only preliminary steps are evident in the HTML editors currently on the market. An example of this strategy is the 508 Accessibility Suite from UsableNet Inc. for Macromedia Dreamweaver and UltraDev, a downloadable software extension that supports HTML authors in testing Web s ites and making them accessible. [iii]

Automation addresses the two key factors that are significant in the current prolific production of inaccessible Web pages. The first is lack of awareness, or more specifically, the possibility of authoring Web pages with little or no understanding of accessibility issues related to HTML programming. A second problem is the lack of motivation to do repetitive, complicated or time consuming activities that may be viewed as unimportant. The key to increasing the accessibility of the Web is to leverage the power of computers to do the repetitive and guideline intensive work instead of asking people to scrutinize and change their own authoring habits. With the proliferation of GUI word processor style HTML editors, a unique opportunity for including accessibility automation presents itself.

In recent years the education sector has witnessed an exponential growth in the area of courseware authoring tools, or learning content management systems (LCMS) to assist in presentation of Web-based curriculum and in performing class management tasks. Significant gains can be made if courseware authoring tool developers take steps to eliminate barriers to access in the web pages generated automatically by their programs, as well as those uploaded from an external source.[iv]

Considerable work in this area has already been completed by WAI in the form of the Authoring Tool Accessibility Guidelines (ATAG) 1.0 .[v] The associated guidelines and checkpoints in the WAI document provide a useful framework for consideration of the current challenges and the opportunities at hand for courseware authoring tool developers. In this paper, the ATAG guidelines have been used as criteria for analysis of several courseware products reviewed in a recent study at the Adaptive Technology Resource Centre, University of Toronto[vi]

Guideline 1. Support accessible authoring practices.

> *1.1 Ensure that the author can produce accessible content in the markup language(s) supported by the tool. [Priority 1]*
>
> *1.2 Ensure that the tool preserves all accessibility information during authoring, transformations, and conversions. [Priority 1]*

Compliance with checkpoints 1.1, 1.2 and 1.3 relates to two types of HTML authoring. In some cases the products reviewed allow online editing of HTML through a text field in the client browser, allowing the author complete control of the HTML markup. However, a more recent trend toward online WSYWYG editors, based on Java technology is more problematic as the underlying code is not apparent to the author. Courseware products generally allow the course designer to upload documents authored outside of the courseware tool without alteration to the HTML markup or compromising of the accessibility information inherent in the pages. In this latter instance, clearly the author determines how the HTML code will be written or edited.

BEST COPY AVAILABLE

> *1.3 Ensure that when the tool automatically generates markup it conforms to the W3C's Web Content Accessibility Guidelines 1.0 [WCAG10]. [Relative Priority]*
> *1.4 Ensure that templates provided by the tool conform to the Web Content Accessibility Guidelines 1.0 [WCAG10]. [Relative Priority]*

Checkpoints 1.3 and 1.4 are indeed one of the main areas where developers of courseware authoring tools need to focus their efforts. In most cases, material generated through automatic functions or templates cannot be easily edited by the designer, if at all. Potentially, this may act as a barrier to accessible design. However, with some further effort, it could as easily become an important support in the creation of accessible resources, with no need for specialized knowledge or training on the part of the designer.

Of particular importance is the integration of accessibility features into tools used for synchronous communication. The ATRC has developed a prototype of an accessible chat utility, designed with specific attention to the needs of screen reader users. [vii] E-College has also created an alternative interface for text -based rendering of chat content, which will also be highlighted.

Guideline 2. Generate standard markup.

> *2.1 Use the latest versions of W3C Recommendations when they are available and appropriate for a task. [Priority 2]*

Some of the W3C standards recommended in the context of Checkpoint 2.1 may be seen by courseware authoring tool developers as unfeasible because they are not yet well supported by mainstream browsers. Standards mentioned in this section of the Authoring Tool Guidelines include: MathML, XHTML, CSS and SVG. Even if mainstream browsers are unable to render new standards, they facilitate support accessibility by non-standard browsers and alternative output formats. By ensuring that the authoring tool recognizes and preserves elements that are defined in the relevant specification(s), usability may be enhanced for all users, as legacy documents are used in contexts that support newer standards.

> *2.2 Ensure that the tool automatically generates valid markup. [Priority 1]*
> *2.3 If markup produced by the tool does not conform to W3C specifications, inform the author. [Priority 3]*

Checkpoint 2.2 is another crucial signpost for courseware authoring tool developers. While deprecated elements and nonstandard mark up may produce graphical rendering in a satisfactory manner for mainstream browsers, accessibility issues may arise if content is transformed to an alternative modality based on the users preferences. Examples of common practices include use of a header to change the font size, or BLOCKQUOTE to indent a paragraph. Using markup improperly may create a barrier preventing users with specialized software or preferences from understanding the organization of a page, and navigating through it effectively.

Guideline 3. Support the creation of accessible content.

> *3.1 Prompt the author to provide equivalent alternative information (e.g., captions, auditory descriptions, and collated text transcripts for video). [Relative Priority]*

In addition to supporting authors in creation of materials using standard markup Checkpoint 3.1 recommends support through tools and prompts that further enhance accessibility for students with disabilities. An example can be found in WebCT, a company that has taken steps in recent releases to prompt the author for a description when uploading images to a database.

> *3.2 Help the author create structured content and separate information from its presentation. [Relative Priority]*

Checkpoint 3.2 suggests that courseware developers use new standards such as Cascading Style Sheets, XHTML and XML to separate information from its presentation. While these technologies are relatively recent, it is anticipated that they will become more and more common, as we are faced with management of large web sites and dynamic, database driven resources.

3.3 Ensure that prepackaged content conforms to the Web Content Accessibility Guidelines 1.0 [WCAG10]. [Relative Priority]

Recent developments in the publishing industry may increase the significance of this guideline for courseware developers as they are called upon to partner with companies that have traditionally provided educational resources in print formats. Recognizing the need to move digitize educational materials to meet the demands of today's learner, publishing companies such as McGraw-Hill Ryerson and Pearson have taken steps to offer textbooks as content within a courseware environment.

3.4 Do not automatically generate equivalent alternatives. Do not reuse previously authored alternatives without author confirmation, except when the function is known with certainty. [Priority 1]
3.5 Provide functionality for managing, editing, and reusing alternative equivalents for multimedia objects. [Priority 3]

Issues related to Checkpoints 3.4 and 3.5 may be very simple, or quite complex, depending on the nature of the graphical or multimedia components included in the course. Current products all allow the designer to upload files to be used as course content. Examples where alternative equivalent would be required may range from simple ALT text for an image file to captioning or text transcripts for a video or audio file.

Guideline 4. Provide ways of checking and correcting inaccessible content.
4.1 Check for and inform the author of accessibility problems. [Relative Priority]
4.2 Assist authors in correcting accessibility problems. [Relative Priority]
4.3 Allow the author to preserve markup not recognized by the tool. [Priority 2]
4.4 Provide the author with a summary of the document's accessibility status. [Priority 3]
4.5 Allow the author to transform presentation markup that is misused to convey structure into structural markup, and to transform presentation markup used for style into style sheets. [Priority 3]

The checkpoints found in the *Authoring Tools Accessibility Guidelines* related to automation and provision of a validation and repair process are as yet unresolved by courseware products currently on the market. Online tools such as Bobby[viii], or services such as RetroAccess AccessEnable™ [ix] demonstrate the feasibility of providing such support, potentially within a web-based environment. By including the validation and repair process within the upload utility, content added to the courseware could be monitored for compliance with accessibility benchmarks.

Guideline 5. Integrate accessibility solutions into the overall "look and feel".
5.1 Ensure that functionality related to accessible authoring practices is naturally integrated into the overall look and feel of the tool. [Priority 2]
5.2 Ensure that accessible authoring practices supporting Web Content Accessibility Guidelines 1.0 [WCAG10] Priority 1 checkpoints are among the most obvious and easily initiated by the author. [Priority 2]

At such time as prompts, validation tools and repair tools are integrated into a courseware product, it is hoped that, as recommended by Section 5 of the Guidelines, the interface will be integrated with the overall look and feel of the program. Accessibility should be seen as an essential part of the authoring process, not as an add on to the program or an "extra" external step in the process. In the future, courseware products should use models such as these as they move to include tools to support accessible authoring practices.

Guideline 6. Promote accessibility in help and documentation.
6.1 Document all features that promote the production of accessible content. [Priority 1]
6.2 Ensure that creating accessible content is a naturally integrated part of the documentation, including examples. [Priority 2]
6.3 In a dedicated section, document all features of the tool that promote the production of accessible content. [Priority 3]

Checkpoints 6.1, 6.2 and 6.3 indicate that, in addition to automation of accessible design, validation and repair processes through integration of prompts and utilities to support the page author, help and documentation must

BEST COPY AVAILABLE

include explanations of accessibility problems, and should demonstrate solutions with examples. This will support Web authors who may not be familiar with accessibility issues that arise when creating Web content.

Guideline 7. Ensure that the authoring tool is accessible to authors with disabilities.

7.1 Use all applicable operating system and accessibility standards and conventions (Priority 1 for standards and conventions that are essential to accessibility; Priority 2 for those that are important to accessibility; Priority 3 for those that are beneficial to accessibility).
7.2 Allow the author to change the presentation within editing views without affecting the document markup. [Priority 1]
7.3 Allow the author to edit all properties of each element and object in an accessible fashion. [Priority 1]
7.4 Ensure that the editing view allows navigation via the structure of the document in an accessible fashion. [Priority 1]
7.5 Enable editing of the structure of the document in an accessible fashion. [Priority 2]
7.6 Allow the author to search within editing views. [Priority 2]

This final section of the Authoring Tool Accessibility Guidelines addresses issues related to the designer user interface, emphasizing the importance of providing components and utilities that can be accessed by an author using assistive technology. While it is critical to ensure inclusion of learners with disabilities in development of the student interface, it is equally as important to provide support for the educator, instructor or designer with a disability.

While development of "offline" HTML editing software requires consideration of traditional user interface design standards and conventions, provision of the authoring process through a browser instead requires consideration of Web content accessibility standards. A client browser authoring tool offers many of the access advantages inherent in Web-based delivery, including flexibility in presentation, input and output modalities. Using their browser or adaptive software, the author can enlarge the font, navigate the content and utilize authoring utilities, provided the interface has been designed in compliance with WAI *Web Content Accessibility Guidelines*.

Summary:
In summary, authoring and courseware tool developers face challenges, but also have a great opportunity to improve access for all learners. Given that content developers and instructors rely on these tools to create and delivery content, they play an essential role in ensuring the accessibility of educational resources on the Web. As noted in the *Authoring Tool Accessibility Guidelines* it must be recognized that the Web is "both a means of receiving information and communicating information," and "it is important that both the Web content produced and the authoring tool itself be accessible."

One World, One Ethics: Lessons Learned Designing an International E-learning Curriculum for Research Ethics

Mary Harvey
PriorityX Internet Services
United States
mary@priorityx.net

Bob Rice
Field, Information and Training Services
Family Health International
United States
rrice@fhi.org

Abstract: Research ethics training is mandated by many funders supporting research that includes human participants. Most programs are developed specifically for a U.S. audience and almost exclusively reference local institutional policies and U.S. regulations. Family Health International (FHI) developed a ***Research Ethics Training Curriculum*** as an interactive e-Learning aid for international researchers that is easy and fun to use. This curriculum is directed at the "lower end" of computer hardware, common in many international locations. The curriculum is written in non-technical language, was field-tested in four international settings, and is intended and designed for both individual and group educational settings. All materials needed for a group presentation are available "ready-to-go" so that the presenters' preparation work is kept to a minimum. The materials are available as either a stand alone CD-ROM or online through the FHI website at www.fhi.org.

Overview

Family Health International (FHI), an international research and training group that works in the reproductive health field, in collaboration with PriorityX, a web development company, created a *Research Ethics Training Curriculum* (*RETC*). This curriculum is designed to meet the needs of international audiences of biomedical and social science researchers. The curriculum addresses basic elements of research ethics, including the principles of human research ethics, international guidelines, informed consent and ethic review committees. The *Research Ethics Training Curriculum* was developed as an interactive e-Learning aid for international researchers that is easy and fun to use.

This curriculum is directed at the "lower end" of computer hardware, common in many international locations. The curriculum is written in non-technical language, was field-tested in four international settings, and is designed for both individual and group educational settings. The materials are available as either a stand alone CD-ROM or online through the FHI website at www.fhi.org.

To work effectively in low technology settings, no plug-ins, multi-media or single platform programming were used. The program was written entirely in HTML. For the interactive online post-test to store answers and give a final score, JavaScript was utilized. *RETC* was designed for Explorer 3.0 and Netscape 3.0, since those versions are still in use throughout the world. For the web version, large files were divided into smaller files for download purposes keeping in mind 28.8 speed modems. Interactivity was created using pop-up windows for the case study responses to actively involve the learner. Interaction between the learner(s) and the course material is further encouraged via "learner notes" that ask the learner to respond to questions before moving to the next section of the curriculum.

The main messages in the *RETC* are that:

BEST COPY AVAILABLE

Research is good
Research is a privilege
Social progress requires research
Society must trust its researchers
Researchers earn society's trust

Rational

In October of 2000 the World Medical Association (2000) revised the Declaration of Helsinki. Parts of this controversial reaction were in response to placebo-controlled research in the developing world. In April of 2001 the U.S. President's National Bioethics Advisory Commission (2001) issued a comprehensive report on issues in international research. The report, which included research considerations suggested by FHI, offered sweeping recommendations for those sponsoring and conducting research outside the United States.

Ethics in research involving human participants is important as comments from international research sites indicate:

CIOMS (1993): "the ethical implications for research involving human subjects are identical in principle wherever the work is undertaken"

Sharif, S.K. (1998), Kenya: "one of the major problems in the Third World is the weak ethics and scientific committees that review scientific studies"

Benatar, S.R. (2002), South Africa: "the need to build capacity in research ethics as part of the research endeavor"

The *RETC* employs provocative and culturally interesting reproductive health case studies developed by FHI researchers to highlight and discuss various ethics issues with the training participants. The Council for International Organizations of Medical Science (CIOMS, 1993) Guidelines and World Health Organization "Operational Guidelines for Ethics Committees That Review Biomedical Research" (WHO, 2000) are cited as key sources; complete copies of these documents are included in the reference section of the curriculum. Since publication in June 2001, FHI has received numerous positive comments from international research groups about the curriculum's local relevance and applicability. The *RETC* is now a recommended educational tool for organizations such as United States Agency for International Development (USAID), the Centers for Disease Control and Prevention (CDC) and the National Institutes of Health (NIH), among others.

The goal for this e-Learning program is to verify that research investigators, Internal Review Board (IRB) members and staff maintain continuing knowledge of relevant regulations and institutional policies for the protection of human participants.

Design

For the organizer of the group presentation, the *Research Ethics Training Curriculum* is "ready to go" in that very little preparation time is needed on the part of the facilitator. PowerPoint was selected as the presentation format as it is becoming more available around the world, and is fairly easy to use (and allows the facilitator to tailor slides to the specifics of the audience). All needed programs are supplied on the CD-ROM version of *RETC*, including Internet Explorer, Acrobat Reader and Microsoft PowerPoint Reader.

Case studies, learner notes, and the post-test are structured to encourage interaction between the viewer/learner and the subject matter. Examples include shaded learner notes, pop-up windows for case study answers, and a computer graded self-test. Of course, adults learn best and remember what they have learned longer when they actively participate in the learning experience. After completing the course material, learners are encouraged to contact FHI to receive a "certificate of completion" and to be included on a mailing list that will allow them access to research results and materials appropriate to their field of study. The "certificate of completion" is important to participants as it credentials the attendee of the training course, and is a noteworthy wall decoration in a resource-poor setting.

The *RETC* is attractive and visually appealing. Visual images were selected that appeal to an international audience. For example, the lotus flower graphically highlights the main sections of the RETC as it symbolizes "purity and perfection" in many cultures—the goal of a research design when it is implemented.

The *RETC* is available as either a three-ring binder, a CD-ROM, or on the web, catering to different learning/presenting styles. All three choices "interact" with the audience and demand participation—thereby enhancing retention on the part of the learner(s).

The *RETC* is user-friendly. It uses a tabbing system in both the three-ring binder and the navigational layout of the CD-ROM/web site. The objectives, learner notes and self-evaluations are displayed so that the learner is able to quickly and effortlessly identify the key messages. A post-test helps the learner retain important concepts.

The draft *RETC* was reviewed by a number of international research ethics experts at WHO and other research agencies. After thorough review, the *RETC* was field-tested in India, Kenya, Philippines, Zimbabwe and the U.S. The *RETC* uses simple English, given that many of the users of the curriculum will speak English as a second, or even third, language. For example, during the field-testing it was suggested that the word "oversight" was more authoritarian than a local researcher would expect—hence the word "supervision" was substituted instead. Several words and concepts were modified as a result of the field-testing experiences. The *RETC* is now being widely disseminated, mostly in English-speaking countries, including the WHO collaborating centers. Translations in French, Russian, Chinese, Portuguese, and Spanish will be available soon.

PriorityX collaborated with FHI to develop the Training-of-Trainers program (TOT) to insure that facilitators are well prepared to deliver the *RETC* in their research site. In the TOT package, exercises are presented to encourage training rather than presenting, teaching to different kinds of learning, and utilizing the group's knowledge resources.

E-Learning Conference

At the conference, the presenters intend to present and discuss, in a participative, adult-centered educational format, representative pieces of the *RETC* including the Self-Study guide in action, sample best practices from the Training-of-Trainers guide, sample slides from the PowerPoint presentation for presenters and the post-test. Additionally, attendees will receive copies of the *RETC* CD-ROM.

Introducing the Idea of Sustained Query Exposure in the Context of Language Vocabulary Learning

Daniel C Heesch
Department of Computing, Imperial College
180 Queen's Gate, London SW7 2BZ, England
dh500@doc.ic.ac.uk

Abstract: This paper describes and motivates the novel idea of sustained query exposure as a form of passive knowledge consolidation and illustrates its use in the context of a basic pool-sink vocabulary model. The effectiveness of this technique hinges on a well-designed graphical user interface (GUI) that extends and facilitates the interaction between user and query objects. One such GUI is presented in this paper.

1 Introduction

Most of what we learn is forgotten after a short period of time. Considering the amount of largely redundant data with which our cognitive apparatus is continuously bombarded, this tendency to forget is a blessing and deserves being ranked as a chief adaptation against information overload. It becomes a curse, however, whenever there is a need for selective long-term memorization. As was first described by the German psychologist Ebbinghaus, recall ability decreases at an exponential rate (Ebbinghaus **1913**), a relationship that has been validated ever since (see for example Bahrick **1984** and Bahrick **&** Phelps **1987**). Methods devised to overcome this degradation tend to belong to one of two learning paradigms, namely associative learning and staggered learning. The latter is based on the observation that each time a periodical review takes place of the information to be learnt, recall ability does not only jump to its initial level but, more importantly, the rate of subsequent decay decreases such that retention is ensured for progressively longer intervals (Bahrick et al. **1993**). The positive effect of staggered learning on recall ability can be enhanced by excluding from reviews items the student has successfully recalled during previous reviews, a learning mode known as selective learning. **A** few software systems exist that provide support for such selective, staggered learning of foreign language vocabularies (see for example Raedle **2002** which is based on a cardboard predecessor (Leitner **1984**)). Typically, queries that are answered incorrectly are retained in the system for subsequent reviews. For most of its life cycle, a query is hidden away from the user's sight and it is only for brief moments that it is brought back to the attention of the user. In the pre-computer era, practicality may have offered itself **as** a plausible rationale for this property. However, recognizing the flexibility that can be offered by graphical user interfaces, this seems like an unnecessary constraint and more like a relict of the cardboard era. We instead advocate an approach which we shall refer to as sustained query exposure. The principal idea is to display every query previously answered incorrectly in the periphery of the user interface until that query is posed again and answered correctly. By thus keeping incorrect queries visually accessible following their explicit exposure, further interaction between user and query becomes possible, providing potential for the query to "sink in" further.

This visualization is built around a language learning model which has the desirable property that the number of incorrectly answered queries held back for a subsequent review is kept relatively constant (sink size constancy).

The report is organized in two parts. The first part introduces the underlying model, in particular the method used to achieve sink size constancy, and discusses performance measures that can be derived from it. The second part provides a description of the graphical user interface.

BEST COPY AVAILABLE

The system presented here is based on a simple pool-sink learning model as depicted in Figure 1. The queries are Spanish verbs which initially reside in a pool that is accessed to obtain a new query with probability p. If the query is answered correctly, it is marked as successfully learnt and excluded from the learning session. If the answer is incorrect, the query enters a sink which is accessed during each round with probability $q = 1\text{-}p$. We can thus distinguish between two kinds of queries which we shall refer to as type A (pool) and type B (sink) queries.

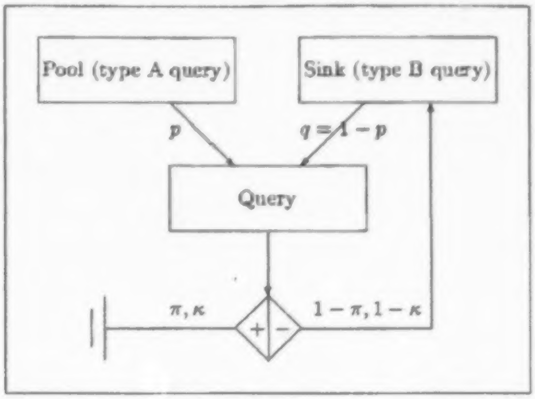

Figure 1: Queries are either drawn from the pool (new queries) or from a sink (incorrectly answered queries). The variables determining the word flow are the probabilities p, q, π and κ (see text for details).

2.1 Fixed sink capacity

The sink is assigned a fixed capacity and the word flow through the system is regulated with the aim of keeping the sink level close to its capacity. This system constraint is desirable not only for the purpose of visualization. For staggered learning to be effective, the user ought not to be exposed to a type B query until some time after the first encounter (time between exposures = TBE). This requirement of a minimum TBE can be met by ensuring that a certain number of queries may enter the sink before they are retrieved. It is not desirable, however, to allow the unlimited accumulation of queries as this would lead to an unacceptable prolongation of the TBE, thus the need for an upper bound. Keeping the sink level constant means that, for a competent user, pressure on the sink is low and TBE will be long. For a less competent user, pressure on the sink is higher and queries need to be retrieved more frequently. Hence, TBE increases with the competency level of the user.

The system variable that regulates the flux through the system is the probability, p, of a query being drawn from the pool. The external variables that affect flow characteristics and on which we have little influence relate to user performance. Specifically, they are the probabilities π and κ of the user correctly answering a query of type A and B, respectively. p, τ and κ provide a complete description of the system. Our aim is to achieve a dynamic equilibrium of the system with the sink level remaining stable and the rate of inflow of new queries being balanced by an equal rate of outflow of correctly answered queries. Let s_t be the sink level at time t, then the state of the sink at time $t+1$ is given by the stochastic equation

$$s_{t+1} = s_t + \mathrm{w}\,, \quad \text{where w is a random variable with}$$

$$\mathrm{w} = \begin{cases} 1 & \text{with probability} \quad p(1-\pi) \\ -1 & \text{with probability} \quad (1-p)\kappa \\ 0 & \text{with probability} \quad 1-p(1-\pi)-(1-p)\kappa \end{cases}$$

At equilibrium, the expectation of w, $E(w)$, is zero, that is $E(w) = \mathrm{p}(1-\pi) - (1-p)\kappa = 0$ and hence

$$p = \frac{\kappa}{1-\pi+\kappa}. \tag{1}$$

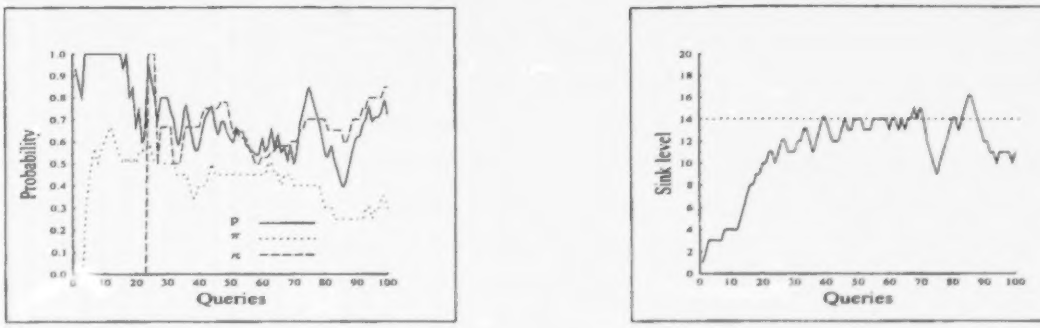

Figure 2: Left: a typical learning session over 100 queries. Initially, a query is likely to come from the pool (p is high) so as to fill the sink. As the sink approaches its capacity, p decreases. Right: sink level constancy is achieved by continuously updating the probability p of a query being obtained from the pool.

As the user performs better on either type of query (increase in κ or π), the probability p of presenting a fresh query in the next round increases. To ensure that the system reaches the equilibrium in the first place and finds back to it when being displaced (as a result of variations in κ and π), we first introduce the random variable w_i, representing the value of w on the $(t+i)$th trial. Then,

$$E(s_{t+n}) = s_t + \sum_{i=1}^{n} E(w_i)$$

and since the random variables w_i are independent and have the same distribution as w, this is just $E(s_{t+n}) = s_t + nE(w)$. To reach the capacity c after d steps, we want to choose p such that

$$E(s_{t+d}) = s_t + dE(w) = s_t + d(p(1-\pi+\kappa) - d\kappa) = c \qquad \text{and thus}$$

$$p = \frac{c - s_t}{d - d\pi + d\kappa}.$$

The more the current state lies below the capacity, the greater is the influx of new queries. Updating p thus requires knowledge of the values of π and κ. In the present model these performance values are obtained by determining the running average over the last 20 queries of either type.

2.2 Measuring performance

From this model we can derive a simple performance measure, namely the value of the variable p. The higher p the greater the proportion of queries answered correctly. It follows from the sink capacity constraint and directly from equation 1 that $p = 1$ implies that all queries are of type A and are answered correctly ($\pi = 1$), while $p = 0$ implies that all queries are of type B and are answered incorrectly ($\kappa = 0$). p varies during any one particular session owing to user/query specific variations in π and κ. The mean value of p over all queries during one session thus provides an estimate of overall performance while the variance in p is an indicator of the extent of inter-query consistency in performance. The variations in p, π and κ during a typical learning session are depicted in Figure 2. It also illustrates how continuous adjustment of p helps to keep the sink level within narrow bounds around the sink capacity ($c = 14$).

3 Sink visualization

With the sink level thus being kept relatively constant, the stage is now set for a visualization of the sink content. The center of the display accommodates three text fields to display a query, enter a reply and inform the user about correctness and possible alternatives. Incorrectly answered queries are displayed as spheres on a concentric circle around this center as shown in Figure 3. The query string is printed across each sphere and for aesthetic purposes, the radii of the query spheres vary with query length.

To increase interaction between the user and the periphery, each query is assigned an electric charge, with the charge depending on query length and thus the radius of the sphere. Spheres repel each other and whenever a new query is taken up into or leaves the set, the new set of queries are allowed to find a stable arrangement subject to the electrostatic forces acting between them. The movement towards equilibrium is recorded and displayed as a short animation sequence of one to two seconds after which the user is provided with a new query. In addition to thus drawing the user's attention towards the periphery and thereby facilitating interaction between user and incorrectly answered queries, it also gives the user a form of immediate visual feedback. If the current query was obtained from the sink and is again answered incorrectly, the set remains unchanged and no animation sequence will be shown. Instead, the colour of the respective query sphere will turn darker as shown in Figure 3.

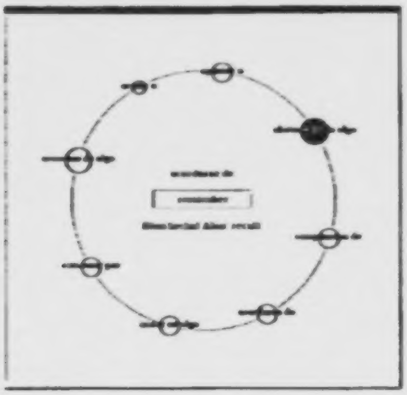

Figure 3: User interface and sink visualization. Animation and colour changes are included to facilitate interaction between user and periphery. See text for details.

4 Outlook

This paper introduces the idea of sustained query exposure and illustrates its potential use in the context of a staggered learning model for Spanish verbs. At this stage comparative performance evaluation becomes a key necessity in order to corroborate our claim about the potential effectiveness of this proposed technique of passive knowledge consolidation. Additional information that may be of interest concerns the precise scope and type of visual interaction between user and interface. This information, which could be gathered using existing eye-tracker technology, is likely to motivate further improvements of the interface.

Abstract: To address the increasing demands placed on adults entering today's workforce, this study involved the development of an instructional approach designed to teach adults strategies for writing effectively in an electronic context through a combination of face-to-face and electronic-based tutorial sessions. The instructional approach was developed based on a reciprocal teaching framework and a goal was to situate the learning within a meaningful, work-related context through electronic discussions. Specifically, the objectives of this study were 1) to understand the experiences of participants enrolled in workforce literacy programs, 2) to assess the impact of an instructional protocol, developed to teach how to express or explain a viewpoint, ask pertinent questions, and write effective responses, on the quality of writing, and 3) to examine if changes occurred in participant attitudes toward writing using computers.

Introduction

Writing in electronic spaces has changed most workplaces. For example, a poll conducted by the Gallup Organization, Inc. estimates that ninety percent of large companies, sixty-four percent of mid-sized companies, and forty-two percent of small firms currently use e-mail systems. The same poll found that more than forty million employees correspond via e-mail, and the number is expected to increase by about twenty percent each year (Kopp, 1998). Further, "e-mail has become the most-used communication tool on the job" in the United States and in Canada (Merrick, 2000, p.17). In addition to the steady increase of e-mail in today's workplaces, there also has been an escalation in the need to write in electronic contexts.

With the continual increase of electronic writing in various workplaces, it becomes evident that workforce literacy programs must begin to reflect the changing demands of today's workplaces to more adequately assist adult learners in finding and maintaining employment. However, given the growing need to communicate effectively within an electronic environment, it must be recognized that computer exposure is not adequate preparation for adults entering the workforce. Research is needed to establish an instructional design that may support individuals in learning how to use literacy skills effectively within a technological context.

The term Digital Divide came to public attention after a 1995 study by the Markle Foundation revealed that the "same divergence found in society along cultural and racial lines is found online and offline" (CNET News.com, 1997). Many participants in workforce preparation programs are involved in these programs because of barriers to maintaining employment. Although these barriers may occur for a variety of reasons, those attending the programs are often dealing with issues of unemployment. Research suggests that patterns of technology access often mirror existing inequalities rather than mitigate them (Schofield & Davidson, 1998) and if corrective steps are not taken, technology may worsen rather than solve equity disparities (Serim, 1999). Thus, it is essential that workforce literacy programs address these issues and provide opportunities for this gap to be lessened. Reddick, Boucher, and Groseilliers (2000), in their report on technology in Canada, stated "the levels of awareness and the use of these new technologies and services are highly polarized along social class and generational lines, creating the digital divide" (p.1).

Technology integration within workforce preparation programs is needed, especially after long-term repercussions are considered in the case that adult learners are not given adequate preparation for electronic environments in the workplace. For many adults attempting to enter or re-enter the workforce, the addition of new technological demands within workplaces only further multiplies the obstacles to overcome. Unfortunately, many workforce literacy programs typically have not adapted their instruction and curricula to reflect the ever-increasing presence of technology within today's workforce, which therefore may impact participant ability to successfully maintain employment. This study involved the development and assessment of an e-learning context designed to provide instructional support for developing strategies for effective e-literacy writing to adults enrolled in workforce preparation programs.

The Study

The goal of this research was to design and assess an elearning instructional context aimed at facilitating the development of skills for writing in electronic spaces. This study involves the development of an instructional approach designed to teach adults strategies for writing effectively in an electronic context through a combination of face-to-face and electronic tutorial sessions. The instructional approach was developed based on a reciprocal teaching framework and the goal was to situate the learning within a meaningful, work-related context through electronic discussions. The objectives of the study include the following: to understand the experiences of participants enrolled in workforce literacy programs; to assess the impact of an instructional protocol (developed to teach how to express or explain a viewpoint, ask pertinent questions, and write effective responses) on the quality of writing and; to examine if changes occurred in participant attitudes toward writing using computers.

Twenty-two participants (ages 18-48, mean 29.8) from the Annapolis Valley Work Centre took part in this study. All participants had some form of barrier to employment; further, all had been either out of employment for a significant period of time or had never been employed and were receiving social assistance. In all cases, participants felt they would be better prepared for employment if they could improve their ability to communicate electronically.

Basic computer instruction was provided to the participants using IBM Thinkpads, which they used throughout the study. When participants felt comfortable using the laptop computers, they completed an introductory session prior to instruction, which involved making an entry into the electronic discussion group after examining a case study.

Instruction was based on a reciprocal model of instruction and consisted of eleven forty-minute sessions, summarized in Table 1, which focused on three specific writing strategies used when making electronic discussion entries. Instruction was also founded in context pertinent to workforce preparation. Strategy modeling tutorials were primarily grounded in face-to-face interaction. Guided practice sessions involved both face-to-face and electronic instruction and strategy use. Independent practice tutorials consisted of electronic instruction and strategy implementation. Session 10 entailed face-to-face guidance in addition to electronic strategy use while session 11 involved electronic, independent strategy use.

During the instructional phase, participants worked in heterogeneous small groups with a research assistant during their regular class hours at the Annapolis Valley Work Centre. Throughout this time, participants received a protocol for instruction for the three writing strategies. The gradual shifting of responsibility in reciprocal teaching (Palinscar & Brown, 1984) was embedded in the nature of the sessions. Participants used worksheets and study guides prior to making their electronic discussion group entries throughout the tutorial sessions.

Table 1

Description of Instructional Protocol

Session #	Strategy	Description
1	Explaining/Expressing a Viewpoint	Modeling of Strategy
2		Guided Practice
3		Independent Practice
4	Asking Pertinent Questions	Modeling of Strategy
5		Guided Practice
6		Independent Practice
7	Writing Effective Responses	Modeling of Strategy
8		Guided Practice
9		Independent Practice
10	All 3 Strategies	Guided Use of Strategies
11		Independent Use of Strategies

Findings

A computer usage survey completed prior to instruction reflected participant experience with, and attitude toward, computers. Sixty-eight percent of participants had used e-mail while 41% had used chat groups prior to this study. There was also diversity in the frequency of computer use among participants. For example, 14% of the participants categorized themselves as heavy computer users, another 14% felt they were light computer users while another 14% considered themselves to be infrequent users. Additionally, although 59% of the participants had used a computer within seven days prior to participating in the study, 62% of those participants had used a computer for playing games while only 38% used a computer for word-processing and 46% for writing an e-mail message. These findings may suggest that although some participants are using computers, they are not necessarily gaining sufficient experience communicating with computers. Further, at the beginning of the study, 36% of the participants specifically identified writing as a significant barrier for them with regard to finding and maintaining employment.

The instructional protocol was based on reciprocal teaching, in which there was a combination of face-to-face and electronic tutorial sessions, as depicted in Table 1. This blend of instructional delivery proved to be an effective method for teaching adult learners writing strategies necessary for eliteracy. Throughout the sessions, participants consistently requested information regarding computer use. The prompts were aimed primarily at basic computer skills needed to participate in electronic discussions. This suggests that the participants' limited computer experience and comfort level may have prevented independent participation in the instruction, had it been offered without the face-to-face component. One participant's comment reveals the importance of the face-to-face interaction received throughout the instruction: "I liked that you didn't just throw us in there and expect us to know what to do right away."

To assess change in writing quality after instruction, the electronic discussion entries created during an introductory session and entries made during the final independent session were compared. Pre- and post-instruction number of words did not differ (pre-instructional mean 79 and post-instructional mean 68, t $(20) = 1.77$, $p = .092$). However, participants used an increased number of sentences after instruction than they did prior to instruction (pre-instructional mean 3.5 and post-instructional mean 4.9 (t $(20) = 3.24$, $p =$ .004). This suggests that writing processes were changing; it appeared as though participants began to make more intentional, thoughtful decisions about their writing. Further, the comparison of these two groups of entries showed that 95% of participant entries contained an increased amount of explanation to support viewpoints generated. These findings suggest improvements to participants' written communication; relevant viewpoints were explained instead of including irrelevant, isolated opinions. Overall quality of participants' writing was scored using a modification of the TOWL-3. Results suggest significantly higher scores following instruction (pre-instructional mean 19.2 and post-instructional mean of 22.9 with 29 being the maximum score, $t\,(20) = 2.43$, $p = .024$). Explanatory quality of the participants' arguments was also assessed using a 5point scale. This reliable scale indicated that arguments were stronger after instruction than before (pre-instruction 1.5 and post-instruction 4.7, $t\,(19) = 12.58$, $p = .001$).

Participant attitudes toward writing also appeared to change. Prior to the study, some participants revealed hesitation surrounding the writing process, as they were concerned with the aesthetics of their handwriting (some experienced difficulty with the mechanics of letter formation). After participating in the electronic discussions as a part of the instructional protocol, those same participants described writing using computers as being much more enjoyable than writing via the more traditional methods.

Conclusions

Workforce literacy programs must provide opportunities for learners to gain experience using technologies hat are prevalent in the workforce, as it may directly increase participants' chances of successfully finding and maintaining employment. However, it must also be recognized that adequate instruction is needed to assist learners in using these technologies effectively for communication, as a certain level of communication skills is essential to use various components of technology such as e-mail and electronic discussion groups. Due to the overwhelming population of adult learners who do not yet possess the necessary skills to independently participate in electronic instruction, it becomes evident that face-to-face and electronic instruction complement one another through reciprocal teaching and may provide adult learners with an optimum opportunity to gain experience using communication technologies within a meaningful, work-related context while engaging in the process of becoming e-literate for the workforce of the 21st century.

Exploring the Effect of Visual Complexity on Music Interval Recognition Tasks Involving User-Generated Images

George J. Henik[1] and Christopher Allen[2]
Educational Communication and Technology Program
New York University
United States
ed.ss.webmaster@nyu.edu[1] and allenchg@shu.edu[2]

Abstract: 36 volunteers were assigned to either a high (19) or low (17) visually complex (VC) treatment group and are given an online drawing environment in which they are to generate images based on musical intervals. They are then tested on their recall of the intervals by using their own images as choices. While the low visually complex group significantly improved, several factors including time may have played a more important role. Results are explained with respect to dual coding theory (Clark & Paivio, 1991; Paivio, 1971, 1990) and the generative theory of reading comprehension (Wittrock, 1990).

When examining multimedia learning environments, the most noticeable omissions occur when applied to music. One of the largest obstacles to designing effective music software has been hardware; that is computers that were being used for instruction were not capable of effectively reproducing authentic sound. Though the hardware has improved, there is little research on how to effectively use computers to teach music. In attempting to design instructional software that seeks to teach any aspect of music (performance, composition, history, or theory), it is imperative to understand how one processes music and how that information relates back to an effective design of musical educational media.

This pilot study will investigate the effect visual complexity may have on music interval recognition tasks to assist in future design decisions. Through the use of user generated images possible connections between aural information, visual information, and verbal information may be explored. By making a connection between these modalities, a more effective method for designing music education software may be possible.

Theoretical Foundation

There are a number of educational theories currently attempting to explain how individuals process new information. Mayer proposes a Cognitive Theory of Multimedia Learning alternately referred to as the Generative Theory of Multimedia Learning (Mayer, 1997, 1999; Mayer & Sims, 1994; Moreno & Mayer, 2000) in which he merges dual coding theory (Clark & Paivio, 1991; Paivio, 1971, 1990) and the generative theory of reading comprehension (Wittrock, 1990). Within the theoretical framework of the Cognitive Theory of Multimedia Learning, an individual perceives the information to be processed in one of two formats: words (verbal) or images (nonverbal) (Mayer, 2001). As the information is received either visually or aurally the learner selects the pieces that are pertinent to their knowledge acquisition. Depending how the individual originally learned or coded the information, either as a word or image, depends on how that information is subsequently recalled.

Cognitive load theory attempts to explain how an individual appropriates a level of mental processing energy to a specific amount of information (Cooper, 1990). In attempting to learn new information, the learner is placed in an environment where they are receiving a variety of information stimuli in potentially different modes. The amount of cognitive load can increase depending on the information itself, the presentation of the information, or the situation in which the learner is engaged. As cognitive load increases the learner becomes frustrated, makes mistakes, and generally performs poorly on the task they are attempting to complete (Keyes & Krul, 1992).

Increasingly, online multimedia systems are integrating greater amounts of visual information and potentially increasing the level of complexity within the information architecture. According to Keyes & Krul (1992), this complexity refers to "the number of information items into the number of relationships among them" (p. 122). Visual complexity is circumscribed as the amount of visual item interactivity contained within an image and limiting that information to the primary representation or more simply how much visual information is "packed" into the primary image. This information is generated through the intersection of lines, colors, tones, and texture gradients (Gibson, 1979). It is therefore believed that by incorporating more information within an image, the greater the level of visual complexity.

Considering cognitive load is increased as the amount of information being processed increases, the conjecture is that visual complexity will affect cognitive load. The greater the visual complexity, the greater the cognitive load. However, there is the possibility that a lack of visual complexity will also affect cognitive load in that the viewer will be required to expend mental energy to fill in the information not being provided.

The research involving educational implications of musical auditory processing with respect to images is scarce. Many studies look at how verbal and visual information are connected (Mayer, 1997, 1999; Mayer & Sims, 1994; Moreno & Mayer, 2000) or verbal and nonverbal information (Clark & Paivio, 1991). Other research indicates a deeper semantic connection between the visual and auditory modalities (Datteri 2000).

Clark, Stamm, Sussman, and Weitz (1974) examined recall of sounds that could be labeled, such as water or a saw, versus those that could not be easily labeled, such as a lathe or a calculator. The designation of "labelable" (p. 177) sounds was determined through a pilot study. When these sounds were mixed in with other sounds and subjects were asked to indicate whether or not they have heard that sound before, the "labelable" sounds were selected significantly more than "nonlabelable" sounds. They concluded that dual coding theory (Clark & Paivio, 1991; Paivio, 1971, 1990) could be expanded to sounds as well.

Lipscomb and Kendall (1994) examined the interaction between music soundtracks and film, suggesting that a model of motion picture perception must focus on the "*source* of meaning within both the auditory and visual modalities" (p. 88). The decisions of the appropriateness of a film score is based on the listener's past experience and is therefore "individual-specific." (p. 91).

In another study that examined verbal labels to music, Hiraoka and Umemoto (1981) used 19th and 20th Century classical excerpts to examine how verbal labels affect the memory recall of musical passages. Creating four groups (three with titles and one without), each group was given a booklet with the six titles. Each passage was played, and the subjects had to read the title of that passage, and then listen to the passage, forming an image of the music based on its title. Participants described their images on paper, and rated the "vividness of the image" on a scale from 1 to 5, with 5 being very vivid, followed by a post-treatment test. The study concluded that since these subjects made their own imagery they seemed to use it as a retrieval cue that resulted in the higher recognition scores.

So it seems that there may be a dual coding process that exists within the auditory modality, and that by having the user generate meaning or images, a stronger connection can be made. Wittrock's generative theory of reading comprehension (1990) discusses the importance in generative meaning through reading. Could this process be similar to verbal information in the sense of language?

There are several known facts about processing music. Whereas the visual modality is distributed spatially the auditory modality is distributed temporally. Also, the assumption that music is processed in the same way as language is far from clear. Sloboda (1985) expounds a clear comparison of music versus language, and finds that the perception in music is not as complete and automatic as it occurs in language, even for trained musicians. In this sense there seems to be two different systems that exist within the auditory modality, one for verbal information and one for auditory information.

Even if there are two different systems that exist, perhaps there are similarities in the way information is processed. Based on these points, it seems that if a user was able to generate an image based on a music interval, then a stronger connection could be made between the visual and aural modalities that would result in the user learning the intervals more effectively. What is the effect of user-generated images on interval recognition? What is the effect of high and low visual complexity on music interval recognition tasks?

Methods

Research Questions:

1. What is the effect of user-generated images on musical interval recognition tasks?
2. What is the effect of high and low visual complexity utilizing user-generated images on musical interval recognition tasks?
3. What is the relationship between user-generated images in high and low visual complexity groups for interval recognition and a) prior music knowledge, b) prior drawing knowledge, c) music interest and d) drawing interest?

Sample: The sample consisted of 36 graduate students who do not have a strong music background though do have a mixed background in graphic design. There were two intact groups from two semesters, each group was assigned to either a high (19) or low (17) visually complex treatment.

Materials: The experiment involved the use of a web-based drawing program developed in Macromedia's Flash 5.0. The user-generated images based on musical intervals were saved in a database and used later to test the participants' interval recognition. One group will have a very simple interface (Low Treatment

Group-LTG) while the other will be more complex (High Treatment Group- HTG) using more elements of interactivity such as a working keyboard (HTG) vs a sound button (LTG), tab-type pallets (HTG) vs all pallets laid out (LTG), and the option to continue (HTG) vs a timed treatment (LTG). Other variables were prior music and drawing experience, the number of times the keyboard or music buttons were pushed, and the time of the second treatment group. Each computer used had access to the Internet, a set of headphones for each user, and the Flash 5 browser plug-in.

Procedures: Learners were given three different musical intervals to memorize (Major 3rd, Perfect 4th, and Tritone). The low visual complex group had 5 minutes for each, while the high VC group could continue at any time. While listening to the intervals they were asked to draw a picture that represents to them what that interval sounds like. After having drawn pictures of all three, a post-test was administered, but this time each user had their own picture that they used as a cue to choose an answer. The entire experiment took between 25 and 35 minutes, with all the data collected through the use of an online database.

Results

For the first question, "What is the effect of user-generated images on interval recognition?" a paired t-test was conducted, using the interval pre- and post- tests as the dependent measure and the drawing program as the independent measure for each group. While the low visually complex group significantly improved (t=2.759, $\underline{p}$=.014), the high visually complex group did not (t=.965, p=.349).

For the second question, "What is the effect of high and low visual complexity utilizing user-generated images on musical interval recognition tasks?" an unpaired t-test was conducted between the pre and post-test scores of each group. The pretest was not significant, though the posttest showed the low visually complex group was significantly larger (t=2.156, $\underline{p}$=.038).

For the third question, "What is the relationship between user-generated images for interval recognition and a) prior music knowledge, b) prior drawing knowledge, c) music interest and d) drawing interest?" a multiple regression was conducted for the first group using answers from the questionnaire to rate prior music and drawing knowledge as the independent variables, and their answers from the post-test as the dependent measure. A series of multiple regressions for the low visually complex group yielded a significant model ($\underline{F}(4, 12) = 4.284, \underline{p} = .022$) with $\underline{r}^2 = .588$. Based on a correlation table that yielded no significant results, multiple regressions were not conducted on the high visually complex group.

Conclusions

For the low treatment group, the treatment was effective in using the generated images as a visual cue for auditory information, and adds to the body of research that addresses the effectiveness of Web-based instruction. In this sense, there seems to be a system that helps connect auditory information and visual information without either one having a designation of "verbal information" as in dual coding theory (Clark & Paivio, 1991; Paivio, 1971, 1990). This connection is made through the user generating an individually meaningful chunk of information (Wittrock, 1990), in this case an image.

An inverse relationship existed between the level of treatment group and performance, indicating that by increasing the level of visual complexity, instruction degraded. The discrepancy between the groups may be explained through two other ways, however. The biggest difference in the two interfaces was time. In the LTG, the participants were forced to wait a full 5 minutes before being able to go on to the next interval. Meanwhile, the participants in the HTG could continue at their discretion. While some participants in the HTG spent approximately 8 minutes on the treatment section, others spent less than 1 minute; far below the 15 minutes the LTG spent on the actual memorization and drawing tasks.

Another possible explanation for between the LTG and HTG results was the class mindset when the treatment was administered. When students in the HTG were administered the treatment, the classroom was very hot and the treatment date fell during a more stressful point in the semester whereas the LTG received the treatment in a relatively comfortable room during a less stressful time in the semester. This might account for some of the more random answers, and helps to explain why some students spent less than a minute on the entire treatment.

Based on the exit surveys in both groups, students were asked to comment on their experience. Qualitative analysis of these comments revealed that many of the students felt the instructions leading up to the treatment were too verbose and could have been accomplished in a more concise manner. However, the ability to understand the goals of the treatment were mixed. Some individuals understood exactly what was expected of them while others felt the requirements were unclear. Clarity appeared to be a continuous theme in many comments, whether it was the clarity of the directions or how to use the interface.

One of the primary differences between the two treatment groups was a change in the interface. In the first treatment individuals indicated problems associated with the fore and background color panels being spaced too close together. This problem seemed to be alleviated in the second treatment by modifying the interface design because no comments focused on a problem differentiating between the two color palettes. In the second treatment, while individuals did comment on difficulties with the interface, these stemmed from problems associated with the aforementioned directions.

While difficult to assess, because of the minor changes associated with an already difficult interface and complex information structure, the addition of a keyboard as a visual cueing mechanism seemed to have no effect on the overall treatment. However, this is supposition considering individuals in the second treatment were not forced to spend a predetermined length of time on each treatment and could skip ahead.

Considering the element of time, a question raised by this study is exactly what effect does time have on the treatment. One final question how would the results differ if this treatment were run with music students as the participants. Considering there is an incentive to learn and not merely gloss through the treatment the potential to understand the basics of the treatment as well as actually incorporate imagery as a learning method would prove interesting. Since the learners generated their own images, the potential for them to undergo a deeper cognitive process may eventually lead to a more effective method for ear training and music education in general.

A Systematic Review of Technology to Support Adult Learning in Communities of Practice

Gyeong Mi Heo
Department of Educational and Counselling Psychology
McGill University
Montreal, Canada
gheo@po-box.mcgill.ca

Abstract: This paper presents a systematic review regarding how technology supports adult learning in communities of practice. It presents the systematic review procedure that was developed, based on NHS CRD (2001) protocol, from publication sources relevant to the topic. It includes the identification of research from an initial question that is how technology supports adult learning in communities of practice, a search strategy, a study quality assessment, a data extraction strategy and a synthesis of findings. Because most of the pertinent research is qualitative, a typology of qualitative research and a critical appraisal checklist for quality assessment were designed and are presented. The results presented are synthesizing evidence from studies that meet certain quality criteria and they are discussed in terms of (a) the kinds of technologies applied in communities of practice, and (b) successful features of the technology that seem to contribute to learning.

Introduction

The development of computer-mediated communications has led to rapid changes in learning environments. In the professional development literature, particularly, the concepts of "learning communities" and "communities of practice" with asynchronous and synchronous communications are emphasized. Even though many online learning communities and/or communities of practice are created and maintained (e.g., Brown & Gray, 1995; Burk, 2000), there is a lack of clear and helpful guidelines to increase meaningful learning in these contexts (Wenger, 1998). Most of the relevant literature offers models, programs, and projects in relation to online communities in learning environments. However, there are very few organized accounts of the significant, valuable, and reliable evidence regarding the effectiveness of on-line technology for fostering and supporting learning in communities of practice (Owen, 1998; Simich-Dudgeon, 1999). In this context, a systematic review, such as those currently being conducted in the medical and health care field[1] and considered seriously in education[2], seems to be an appropriate research method to produce general statements about the relationships between technology and learning through the synthesis of individual research results.

The research presented here is a systematic review whose purposes are (a) to present an application of the systematic review protocol in educational research on the question of web-based technology to support learning in communities of practice and, (b) based on the results of the systematic review, to examine the effectiveness of technology in communities of practice. This paper presents a preliminary review of the studies in order to test the systematic review process and its feasibility. The following two objectives are identified

- Objective 1: What kinds of technologies were applied to in communities of practice?
- Objective 2: What features of the technology seem to contribute successfully to learning?

The next section introduces the steps involved in conducting such a review.

---

[1] The Cochrane Collaboration (http://www.cochrane.org/)

[2] The Campbell Collaboration (http://www.campbellcollaboration.org/)

Systematic Review

The systematic review is "a review of the evidence on a clearly formulated question that uses systematic and explicit methods to identify, select, and critically appraise relevant primary research, and to extract and analyze data from the studies that are included in the review" (NHS CRD, 2001). The systematic review is a rigorous methodology that has emerged in the fields of medical and health care. The Campbell Collaboration was initiated recently to study the effects of social and educational policies and practices as a sibling organization to the Cochrane Collaboration that prepares and maintains systematic reviews of the effects of interventions in health care (Boruch, Petrosino, & Chalmers, 1999). According to the CRAG (1996), the characteristics of a systematic review in comparison with a traditional literature review are (1) it is more systematic and objective through whole review procedures, and (2) it makes possible to increase power by synthesizing the results of a number of related smaller studies.

Identification of research

As a first step, to develop a search strategy, the research question should be broken down into facets in terms of population (e.g., *adult learning* that includes university education, professional development and workplace training), interventions (e.g., *communities of practice* and *technology*), outcomes (e.g., unrestricted), and study design (e.g., unrestricted). The search conducted with these keywords in the ERIC database and 253 citations were obtained.

Selection of studies

In this step, the obtained citations were selected through two filters for inclusion and exclusion in order to have more retrieval of relevant documents. For an initial selection, abstracts of citations obtained from the previous ERIC search were scanned and selected using the initial criteria for inclusion and exclusion. The second selection was conducted by reading the full texts. At this stage, more detailed criteria were applied and 60 papers were selected for the next step which consisted in assessing the quality of the studies.

Study quality assessment

Next, the quality of the studies in the corpus thus obtained was assessed. For the quality assessment, at first, the type of evidence is characterized according to research methods in educational research – quantitative research and qualitative research. As for the qualitative research is, typically, needed to be subdivided, because most research papers those are included in the review form as the qualitative research rather than quantitative research and each research method has different report styles and required components. The types of qualitative research were: ethnographic research, action research, evaluation research, case study, and design experiments. Sixty citations were categorized according to the criteria for research methods. Among these citations, thirty-eight citations were classified under descriptive reports and/or opinions of experts, and those were excluded in the review. Among the remaining 22 citations, one was an experimental research with quantitative measures, and 21 citations relate to 20 studies were qualitative researches. Therefore, 21 research papers were included for quality assessment.

Then, a critical appraisal checklist was developed for this review to assess the quality of qualitative research studies in terms of credibility and reliability. Hence, the questions are focused on whether a research paper describes each expected component of a study within the category clearly, appropriately, and reliably. The famework underlying the critical appraisal checklist is largely composed of two parts, one regarding general features of research methods (e.g., Introduction, Methods, and Discussion / Implication), and the other for each specific research method. The remaining 20 research papers, other than the experimental study, were assessed through the critical appraisal checklist. According to the results, 11 qualitative studies and one experimental study were selected for inclusion in the review. Thus, qualified evidence was extracted and synthesized to answer the research questions.

Data extraction and Data synthesis

In this pilot review, initially, the author extracted data into a FileMaker Pro5 database, and then, collated and summarized the results of primary studies included.

Results & Discussion

Objective 1: What kinds of technologies were applied in communities of practice?

The technologies that were applied in 12 studies were e-mail, threaded message board, chat room, web pages, electronic bulletin board, forum, online network, mailing lists, web conferencing, listserv, electronic database. Representative examples of synchronous technology are chat room and video conferencing. However, there none of the studies considered video conferencing. In five studies (Fusco, 2000; Harmon, 2000; Milton, 1999; Ohlund, 1999; Powers, 1997), chat applications were used, and, also, these were combined with one or several asynchronous technologies, such as electronic bulletin board, mailing lists, listserve, and e-mail.

All studies report positive effects of technology in each practice. Technology seems to support learning in the following manners:

- To have multiple conversations (Owen, 1999).
- To expand learning experiences through online networks (Brett, 1997; Rusell, 1999).
- To develop an "out-of-class" classroom community (Burns, 1996; Brett, 1997; Edens, 2000).
- To develop collaborative work (Milton, 1999; Ohlund, 1999)

Objective 2: What features of the technology seem to contribute successfully to learning?

Eight of 12 studies were conducted in formal learning environments. That is, learning communities were built within university-based courses. As for the target learners, six studies involved pre-service and/or in-service teachers. Three studies (Edens, 2000; Milton, 1999; Owen, 1998) explored possible factors contributing to the development of an online learning community.

In conclusion, it is possible from the studies reviewed to synthesize the following features to take into account in order to develop an effective online learning community:

1. The purposes of the group should be determined. (Owen, 1998).
2. An atmosphere of respect is required. Participants should respect others' opinions and ideas (Edens, 2000; Owen, 1999; Harmon, 2000; Simich-Dudgeon, 1999).
3. The role of a moderator or facilitator is one of the critical factors (Edens, 2000; Milton, 1999; Owen, 1998).
4. The participation framework may effect the development of online learning communities (Edens, 2000; Owen, 1999; Harmon, 2000).
5. The strategies for facilitating learners' participation should be considered (Brett, 1997; Fusco, 2000; Hirtle, 2000, Harmon, 2000).
6. On the other hand, Edens (2000) and Milton (1999) indicate two difficulties regarding the use of technology in a community: (a) the problems of the software and network itself, and (b) the lack of non-verbal communication cues, such as eye contact and body expression, in electronic written communication.

According to the results of this systematic review, there are several findings having implications for follow-up reviews and further research. First, the search sources should be expanded, for example by deploying more systematical search strategies in the ERIC database, searching the WWW, and hand searching in proceeding papers or journals not included in ERIC search. Second, in order to increase the validity and reliability for the assessment of study quality, the critical appraisal checklist needs to be continuously developed and validated, and two or more researchers should participate in the review. Third, more research needs to be conducted in non-formal learning contexts emphasizing adult learning and various adult learners.

Conclusions

Computer-mediated communication (CMC) makes it possible to interact asynchronously and synchronously at a distance. It can facilitate sharing, negotiating, developing, sustaining, and building knowledge in communities of practice. During this process, learning can be achieved.

Based on the review of 12 studies, the major factors contributing to facilitate learning in communities of practice are: (a) well-defined purposes for the group, (b) an atmosphere of respect among participants, (c) a moderator or facilitator playing an active role, (d) a structured participation framework, and (e) strategies to trigger and maintain participation.

This systematic review shows the positive potential of the systematic review as an effective research method in educational research, at least in the area of educational technology in practice settings. That is, existing variations in practices and general relationships can be examined by synthesizing related qualified data in smaller studies. It suggests that conducting further systematic reviews in this area will be fruitful.

The Professional Development of Human Service Professionals in Rural and Remote Areas: Investigating the Affordances of the Internet

Anthony Herrington
School of Education
Edith Cowan University
Australia
a.herrington@ecu.edu.au

Jan Herrington
School of Communications and Multimedia
Edith Cowan University
Australia
j.herrington@ecu.edu.au

Abstract: This paper is a report of work-in-progress on a project that seeks to identify effective ways in which the Internet can be used to overcome the isolation of human service professionals employed in rural and remote areas. Professionals employed in rural locations in Australia will be surveyed and interviewed with regard to their needs, awareness, use and benefits of the Internet for professional development and support. Guidelines will be produced to document strategies for the design and delivery of effective use of the Internet to support and assist professionals in rural and remote areas.

Introduction

Retaining human service professionals—such as teachers and health care workers—is a huge problem in many rural and remote areas of the world. The overall objective of this paper is to report on work-in-progress that seeks to identify effective ways in which the Internet can be used to overcome the isolation of professionals employed in these remote regions. More specifically, the research described will use surveys and interviews to:

- Identify the *level* of professional development and support that is available through the Internet to professionals working in rural Australia;
- Assess the *use* of this professional development and support, and
- Identify the perceived *needs* and *benefits* of the professional development to the professionals in these remote areas.

The findings of this research will provide a basis for informed decision making on the design, development and provision of professional development and support through the Internet for a wide range of professions working in rural Australia as well as the training needs to access such support.

Background

There is a growing concern that reduced outcomes in health, education, employment and technology in rural Australia have the potential to undermine national cohesion (House of Representatives Standing Committee on Primary Industries and Regional Services, 2000; Regional Australia Summit Steering Committee, 2000). As a consequence, strategic support for rural and regional areas has become a national priority (Anderson, 2001). Recommendations from these reports document specific strategies for establishing improved social infrastructures and equity of services to enable improved health and education outcomes, better employment pathways and improved telecommunications. Attracting and retaining professional and paraprofessional staff in regional and rural areas is recognised as a significant factor in improving many of these outcomes.

Compared to their metropolitan counterparts, rural communities face a number of reduced health outcomes. These include higher mortality rates, higher incidence of cardiovascular disease, preventable accidents, cancer and diabetes, higher rates of youth suicide, higher rates of hospitalisation and reduced access to medical practitioners, nurses, midwives, pharmacists, dentists and other allied health professionals (National Rural Health Alliance, 2001). This trend is also observed in American rural communities (National Rural Health Association, 1998).

Similarly, educational outcomes are reduced for rural compared to metropolitan communities. Schools in rural Australia experience a higher turnover rate of staff than metropolitan schools (Tomlinson, 1994). A high turnover of inexperienced staff results in schools lacking stability and program continuity, with clear disadvantages for students (Human Rights and Equal Opportunity Commission, 2000). The commission has documented the reduced quality of educational outcomes achieved by rural students in respect of literacy, numeracy, retention rates and participation in higher education. While there are initiatives in place to attract professionals not enough research attention is being given to determining effective ways to retain them (Collins, 1999; Murphy & Angelski, 1996, National Rural Health Association, 1998).

The innovative use of information communication technologies (ICT) is argued by a number of researchers as a viable option for providing professional development and support for rural professionals in the areas of health (e.g., Striffler, & Fire, 1999; Sykes, & McIntosh, 1999). The National Rural Health Association (1998) in the United States argues that although much effort has been expended in placement of physicians in rural areas, relatively little has been done to enhance their retention. The association argues that professional isolation is often a reason to leave a rural area and, as in Australia, the association suggests that innovations in information technologies such as the Internet and teleinformatics can become resources for diminishing this isolation.

A number of websites have been developed to provide professional development and support to professionals in rural areas. For example, sites have been developed to provide information, resources and channels of communication for medical, nursing and allied health professionals working in the NSW public health system (Wensley, 1999). Shackcloth (1999) describes a CD-ROM and Internet interactive resource that provides professional development for dentists in rural and remote regions.

In response to the need for continuing professional contact for newly appointed teachers, Herrington and Herrington (2001) have developed a website entitled Mathematics Education on the Web (MEOW) to enable new teachers to keep contacts with their peers and lecturers, and to access curriculum resources. The site comprises: a discussion board, where issues of relevance can be discussed; lesson plan resources, where teachers can download lesson plans to use with their classes; exemplary teaching videos, where teachers can view a variety of teaching strategies demonstrated by expert teachers; and links to a variety of websites including mathematics and professional development resources.

There are some insights into the effectiveness of these and similar professional development and support websites. Watson, Bannan, Clark, and Timmerman (1999) report that in early trials of Internet use, web-based discussion forums proved unsustainable mainly because allied health workers appeared not in the habit of accessing them on a regular basis. However, email-based discussion lists (listservs) appeared to be more successful with participants indicating that this form of communication helped reduce their professional isolation.

Methodology

Using a variety of databases and direct contact with a range of individuals and organisations, the researchers are conducting a systematic review of the literature on the use of web-based resources for the professional development and support of professionals working and living in rural communities. This includes Australian and international literature, together with additional sources of information. The review of the literature focuses on such issues as:

- the professional needs and benefits in relation to web-based professional development and support,
- the factors that facilitate/hinder the professional use of web-based professional development and support

- the design and functionality of resources
- approaches to IT training for professionals

Professionals working in rural areas of Western Australia and Queensland will be selected for the study. These states have been chosen as they both have large remote areas with geographically dispersed rural communities, and both have a long history of responding to the special needs of these communities (as evidenced for example, by both states' extensive distance education and health initiatives). As such they provide a diverse sample from which generalisations can be made.

The professionals will be contacted by mail via relevant government agencies which include the Education Departments of Western Australia and Queensland, Health Departments of Western Australia and Queensland and the Aboriginal Medical Services. A postal questionnaire will be developed and sent to each professional identified as working in a rural area. Surveys will be undertaken to elicit information on:

- demographic data (e.g., age, qualifications, period of employment)
- needs, awareness, use and accessibility of professional development and support that uses ICT
- benefits/drawbacks of professional development and support that uses ICT
- their beliefs about the impact of ICT in ameliorating professional isolation
- perceived barriers to using ICT
- their IT competence

The initial data analysis will be conducted by profession, examining in detail the effectiveness of ICT on overcoming professional isolation. The analysis will:

- assess rural professionals' *use* of web-based professional development and support resources. For example, are they aware of relevant sites? Do they access these sites. What level of interactivity do they engage in?
- identify professionals' perceived *benefits* of web-based professional development and support resources. For example, are relevant sites helpful?
- identify professionals' perceived *needs* for web-based professional development and support resources. For example, what other resources and supports are needed? What further training do they need to benefit from these sites?

The findings from this research will be used to develop a broad analysis of the impact of the Internet on professionals working in rural communities, and its effectiveness in ameliorating professional isolation. In this part of the analysis, particular attention will be paid to:

- identifying any generic impacts of ICT on professions
- identifying impacts which are likely to be pertinent to specific professions
- identifying effective generic design and implementation strategies
- identifying effective design and implementation strategies specific to certain professions

The findings of the analysis will be the basis of a concise draft report that will be distributed to various stakeholders (State and Federal Government agencies, tertiary and higher education institutions, and professional associations) seeking further comments and suggestions. Such information may form the basis of a more informed approach to the retention of professional in rural and remote regions of the world.

Computer Assisted Simulation and Role Playing

Donald R. Hetzner

Department of History/Secondary Social Studies

State University of New York College at Buffalo, USA

Hetznerd@AOL.Com

Social studies education is the least empirical of all the subdisciplines in the social sciences. An influx of computers into classrooms has had little impact on the nature and direction of social studies instruction. E-learning in the social studies usually consists of using materials such as computer based games with simulated environments and the Internet as expository techniques carried out in very traditional classroom settings. This holds true in most classrooms whether there is a computer for every student or every ten students. The average social studies teacher has little experience in integrating e-learning into a complex curriculum that is undergoing mandated change. This is reinforced by college experiences where students model professors housed in traditional academic and professional departments. At most, social studies students are taught to produce Power Point presentations, and the basics of Internet research.

What forms does e-learning take in typical social studies classrooms? Much depends on the school "rules", the use of consumable supplies, and the nature of teacher. At Niagara Falls SHS, where every student has full-time use of a laptop, students are required to keep their computers in backpacks and only take them out at a teacher's request. Why? Because students play computer games, or leave messages for friends. Many schools control access to large numbers of computers by placing them in the library. Unfortunately, in many of those same schools the librarian does not let students sit next to one another. So, there is no such thing as class use of computers in those schools. In other schools there may be several computers or computers for all students but only one printer and that on the teachers desk. Some schools only issue one printer cartridge or one ream of paper to teachers each semester. Last, social studies is so conservative and tradition bound that teachers use computers in ways they recognize.

PowerPoint takes the place of notes and overheads in many classrooms. Teacher after teacher has happily related to me that "I have all my notes and overheads on PowerPoint now." A teacher of Honors Economics in a local high school was given a petition from her students, only half in jest, "no more PowerPoint" one day when I was visiting her student teacher. Teachers in a number of schools have received the same message.

You can tell when teachers are using the Internet rather than manipulative models for instruction. In the not too distant past 5th and 9th grade students built models of the Mesopotamian ziggurat at home and brought them to class. What models are in the rooms are dust covered and usually rather primitive and poorly constructed, the models that were so "dumpy" that students did not take them home. At least one wall is covered with poorly drawn ziggurats. Students search the Web for " ziggurat" and locate and view a rendering of the building and a discussion of ancient Mesopotamia. During this exercise usually at least one student asks, "what do I do now?" Most of the time the teacher's answer is "draw a picture of it!"

Friday is still AV day in the social studies class. Major movies on DVD's such as *Pearl Harbor*, *Enemy at the Gate*, *Band of Brothers*, *Saving Private Ryan*, and *Gladiator* are standard fare despite the on-screen cautions on use. Possibly even more blatant is the use of copyrighted photographs in extensive, 20-30 minute, PowerPoint presentations.

"Experiences in Simulation and Role Playing," a graduate course at the State University College at Buffalo attempts to cope with the above problems by presenting a model of e-learning that is interactive, data-based, and well-integrated with a variety of media. This is a model with the basic purpose of educating secondary social studies students to become active participants in a democracy. Graduate students, all of whom are NYS certified social studies teachers, are instructed in role playing and simulation through participation in activities such as John Gearon's "War or Peace?" and Barbara Olmo's "Pioneers in Arania."

Students are introduced to Statistical Package for the Social Sciences with a data bases from Nan Rothschild's *New York City Neighborhoods: The 18th Century* (Rothschild 1990), and the writer's *Historian: Building a New Nation in 1789* (Hetzner 2000). The Rothschild book focuses on the demographics of NYC Wards in selected years including 1789. *Historian...* is a proprietary database that focuses on the 1st Congress that met in NYC in 1789. It details the socioeconomic, religious, and ethnic backgrounds of the 95 legislators and their fathers, and voting behaviors and political attitudes toward the Constitution and George Washington. Essentially, it is an introduction to quantitative history and the basic evidence used in historical research. To teach students how to ask historical questions they are taught the basics of SPSS and questionnaire design. The process used in class is termed "interviewing the dead." Graduate students work with the database, which contains music clips, cartoons, reproductions of paintings...until they are familiar enough with the processes of historical investigation and materials design to produce their own computer-assisted simulations and role plays. The basic rules are that:

1. Databases must support the simulation/role play, be the basic stand-alone component of the exercise, or gather data from the secondary students on the results of the activity

2. PowerPoint may be used only to present information that would take too long or be awkward/impossible to present in another fashion

3. Audio is the preferred method for having a moderator communicate with participants in an autoinstrucional simulation/role play

4. The Eactivity must be designed to fit into or complement the NYS secondary social studies curriculum

What types of computer databases and simulations/role plays do secondary social studies teachers produce under these guidelines? Graduate students have submitted approximately 45 projects since the requirement for computer-assisted databases was added to course requirements. The following 5 descriptions are of typical student produced databases. Each of the databases is associated with a simulation or role play on the same topic.

1. Terrorism (a hypothetical situation). Following a terrorist incident the Draft is reinstated. The database simulates random selection of draftees and compiles demographics and physical attributes of those selected

2. Political involvement. This database explores the connection between students' political involvement, socioeconomic background, interests (including social studies), and knowledge of current events.

3. "Failure is Impossible" draws its name from the 75th anniversary celebration of the 19th Amendment. This database of women goes from Abigail Adams to Nellie Rodgers Schuler, and includes information on age, religion, politics, and marital state.

4. Conjoined twins. The author of this database and role play teaches 4th grade in a Catholic school-- data can be displayed by nationality, ethnicity, sex, and family background.

5. Heritage of church members. A class member who is an active member of a largely African-American Baptist church compiled, and is now expanding, a database on the history of the church that focuses on the demographics of parishioners. Family data has been gathered on church founders who moved from the South in the 1860's up to the present day. The database is being used in local elementary schools and in the church to foster community.

A more extensive project, carried out in collaboration with teachers who are former *Experiences in Simulation and Role Play* students, is planned for the 2002-2003 academic year. Arrangements have been made for an architectural firm to complete a reconnaissance study of the architectural/historical significance of 1000 buildings in a Western New York village using "Preserve New York" funding. During or following completion of that component, students in social studies and the leadership program at the high school will work with the writer and an associate to carry out an assets study of the community. Secondary students will design questionnaires and interview schedules, interview village residents, process data, and present the findings at a regularly-scheduled Village Board meeting

Computer Assisted Simulation and Role Playing

Donald R. Hetzner

Department of History/Secondary Social Studies

State University of New York College at Buffalo, USA

Hetznerd@AOL.Com

Social studies education is the least empirical of all the subdisciplines in the social sciences. An influx of computers into classrooms has had little impact on the nature and direction of social studies instruction. E-learning in the social studies usually consists of using materials such as computer based games with simulated environments and the Internet as expository techniques carried out in very traditional classroom settings. This holds true in most classrooms whether there is a computer for every student or every ten students. The average social studies teacher has little experience in integrating E-learning into a complex curriculum that is undergoing mandated change. This is reinforced by college experiences where students model professors housed in traditional academic and professional departments. At most, social studies students are taught to produce Power Point presentations, and the basics of Internet research.

What forms does E-learning take in typical social studies classrooms? Much depends on the school "rules", the use of consumable supplies, and the nature of teacher. At Niagara Falls SHS, where every student has full-time use of a laptop, students are required to keep their computers in backpacks and only take them out at a teacher's request. Why? Because students play computer games, or leave messages for friends. Many schools control access to large numbers of computers by placing them in the library. Unfortunately, in many of those same schools the librarian does not let students sit next to one another. So, there is no such thing as class use of computers in those schools. In other schools there may be several computers or computers for all students but only one printer and that on the teachers desk. Some schools only issue one printer cartridge or one ream of paper to teachers each semester. Last, social studies is so conservative and tradition bound that teachers use computers in ways they recognize.

PowerPoint takes the place of notes and overheads in many classrooms. Teacher after teacher has happily related to me that "I have all my notes and overheads on PowerPoint now." Interesting enough, A teacher of Honors Economics in a local high school was given a petition from her students, only half in jest, "no more PowerPoint" one day when I was visiting her student teacher. Teachers in a number of schools have received the same message.

You can tell when teachers are using the Internet rather than manipulative models for instruction. In the not too distant past 5th and 9th grade students built models of the Mesopotamian ziggurat at home and brought them to class. What models are in the rooms are dust covered and usually rather primitive and poorly constructed, the models that were so "dumpy" that students did not take them home. At least one wall is covered with poorly drawn ziggurats. Students search the Web for " ziggurat" and locate and view a rendering of the building and a discussion of ancient Mesopotamia. During this exercise usually at least one student asks, "what do I do now?" Most of the time the teacher's answer is "draw a picture of it!"

Friday is still AV day in the social studies class. Major movies on DVD's such as *Pearl Harbor, Enemy at the Gate, Band of Brothers*, *Saving Private Ryan*, and *Gladiator* are standard fare despite the on-screen cautions on use. Possibly even more blatant is the use of copyrighted photographs in extensive, 20-30 minute, PowerPoint presentations.

"Experiences in Simulation and Role Playing," a graduate course at the State University College at Buffalo attempts to cope with the above problems by presenting a model of Elearning that is interactive, data-based, and well-integrated with a variety of media. This is a model with the basic purpose of educating secondary social studies students to become active participants in a democracy. Developing a Framework of Electronic Literacy for Post-Compulsory, Remote-Access, Virtual Learning Environments

Anne Hewling,
Institute of Educational Technology, The Open University, UK
a.hewling@open.ac.uk

Abstract

This paper reports on a study to develop a framework of electronic literacy for post-compulsory, remote access, virtual learning environments. The study acknowledges previous work on individual aspects of the online experience but seeks, through a variety of qualitative and quantitative techniques, to formulate an over-arching framework applicable to post-compulsory, remote-access education. This not only enables contextualisation of the many different elements involved but also enables further examination of their nature and relative importance in order that the framework may provide a flexible and robust tool for use in electronic instructional design.

Context

Increased global availability of computing technology, particularly of the Internet, offers the potential for collaborative interaction more or less 'anywhere, anytime'. Along with changes in workplace practices associated with global economic change and the consequent need for lifelong learning, these developments have led to a mushrooming of interest in the potential of virtual (i.e. online) learning environments (VLEs) as education delivery mechanisms.

Virtual Learning Environments

The 1999 Commonwealth of Learning (COL) report on a global evaluation of virtual education notes that *'virtual education is an extremely dynamic phenomenon'* (reported in Farrell 2001). Virtual Learning Environments (VLEs) range from local intranets used to supplement face-to-face and traditional education presentations, to entirely Web-based Internet dependent spaces which may have no terrestrial existence other than through the participation of students using the space. VLEs can be as large or as small as the available access technology, potentially offering a gateway to infinite numbers of learners. Barajas & Owen (2000), define VLEs as *'any combination of distance and face-to-face interaction, where some kind of space and time virtuality is present'*. Postle describes three types: *'supplemental or adjunct'* (online delivery is far from being the primary medium of instruction); *'mixed mode'* (online and face-to-face are both significantly important delivery media) and *'wholly online'* (online delivery is the only medium of instruction), (Postle 2002 p 4).

Electronic Literacy

Traditional and virtual classrooms alike require a certain level of literacy in users. In its most well understood form, literacy can be termed as the ability to read and write in a print-text-based environment. The virtual classroom, in common with the traditional one, is a text based environment but the text is situated within an amorphous electronic environment (Kaplan 2001) where sequence and structure are notably different (Richards 2000; Reinking). The dominance of text in both environments suggests that traditional literacy may form the backbone of electronic literacy. It is clear, however, that traditional literacy practices alone will not guarantee success in the electronic world. There is much debate on and around the nature of electronic literacy, most of it focusing on a single specific aspect. Some authors concentrate on its roots in traditional literacy (Koch 2001). Others, on the skills perceived as essential in a computer based environment (Tapper 1997), or as presented by the learner, in ideas of self-efficacy (Eastin & LaRose 1996; Wang & Newlin 2002). Yet others concentrate on adaptation to the specific nature of an environment which lacks social cues (Yates 2001); where presence cannot be assumed (Rourke *et al.* 2000) and where particular opportunities are afforded for constructivist design and practice (Laurillard 1993); collaborative activity (Garrison *et al.* 2000) and vicarious learning (McKendree et al. 1998). Some refer specifically to an academic literacy of the

BEST COPY AVAILABLE

online classroom. Others speak in terms of electronic *literacies* (Kaplan 1995; Warschauer 1999) implying that there is no one definition applicable to all situations and introducing the idea of literacy as social practice (Lankshear et al. 2002; Snyder 2001), in turn encapsulating the idea that an absolute definition of literacy must be *'preposterous'* since meanings are inherently amorphous (Semali 2001).

Background to the Study

Taking up the challenge, from New Literacy Studies, to broaden the traditionally narrow view of literacy and instead *'capture the complexity of real literacy in contemporary society'* (Snyder 2000 p118) where reading and writing *'are only part of what people have to learn to be literate'*, (Snyder 2001 p119; Barton 2001 p95), the primary aim of this research is to develop a framework of electronic literacy for post-compulsory remote-access virtual learning environments. The secondary aim is to begin the process of understanding the nature of the elements within; to determine whether these are primarily aptitudes or more abstract and conceptual; whether they can be defined purely in terms of skills or whether ideas, such as those of space (Cicognani 1998) and place (Mitra & Schwartz 2001), are implied. This will provide a three-dimensional depth to the study and develop understanding of the inter-relationships of the various elements. Consequent to these aims, the study seeks to map contours rather than to produce definitive answers, quantify elements or prescribe limits and will facilitate discussion of the central question –

> ***What does it mean to be an effective, electronically literate, post-compulsory student in a remote-access virtual learning environment?***

The Study

The study has two main stages. First stage data sources have been:

- *Case studies of electronic/online literacy* - an investigation of what researchers have deemed appropriate to explore or evaluate rather than the outcomes they have generated.
- *Examination of 'grey' literature* - in the form of institutional prospectuses and pre-enrolment materials such as suitability questionnaires and demonstration modules, as indicators of education providers' views of the scope of electronic literacy.

In both cases grounded theorising has been used to identify concepts to assist in mapping the overall scope of electronic literacy. Together with understandings from the researcher's own background and previous experience of online teaching and learning, these concepts have been used to inform:

- *Semi-structured interviews* - with online tutors which are being conducted online using synchronous chat facilities. Interviewees have been purposefully sampled from those working in *'wholly online'* and *'mixed-mode'* environments (Postle 2002)
- *A self-completion electronic questionnaire* – being sent to 100 online learners *undertaking 'mixed-mode'* or *'wholly online'* courses (Postle 2002). Questions seek to explore concepts emerging from ongoing analysis, in greater depth.

Responses to the above are being used to facilitate the development of the core categories which will become the elements of the desired framework of electronic literacy.

Emerging Themes

Any study of electronic literacy, as Tapper (1997) notes, requires consideration of an almost infinite number of variables. Analysis for this study so far has indicated areas receiving most overall attention to be:

- Previous experience of computers, not just word processing skills but experience which has developed positive learner attitudes towards, and tolerance of, technology
- Time and place management where learners not only have a sense of advance planning but also perceive the need to balance and contain online learning activity within other life priorities
- Self-sufficiency as a learner including self-motivation, self-discipline, determination and acceptance of the need for learner pro-activity
- Writing, including ability to write reflectively and convert conversational thought into coherent text
- Visual and semiotic understanding and interpretation
- Information processing, interpretation and evaluation

with different groups affording a range of priority ratings within any one area.

The key challenge in applying the outcomes of the later stages of analysis will be in creating a framework which is both robust and flexible enough to provide a useful tool for use in electronic instructional design. It will need to be tested against different groups of learners entering post-compulsory learning as the products of the ebb and flow of curriculum and resourcing tides within widely differing compulsory education systems.

Differential Indexing: A Problem-Authoring Method for Computer-Based Problem Practice

Tsukasa HIRASHIMA, Akira TAKEUCHI
Kyushu Institute of Technology, JAPAN
e-mail: tsukasa@ai.kyutech.ac.jp

Abstract: In this paper, a problem-authoring method is proposed and an example of the implementation of the method is described. In the problem-authoring method, a new problem is characterized using differences from the basic problem. In the problem-authoring environment, a user can make a new problem by changing the basic problem. The changes represent the differences between the new problem and the basic problem. The new problem is then characterized by the differences from the basic problem. We call the problem authoring method "Differential Indexing".

Introduction

Problem practice is a highly private activity. For example, the next problem in the practice should be decided depending on the student's knowledge, learning context, or mistakes. Computer-based problem practice is, then, a promising approach to deal with the private activity. To realize the elaborate form of the practice, the following three factors are indispensable, (1) student model, (2) practice strategy, and (3) practice material, that is, problems. Such computer-based problem practice is often called Intelligent Problem Practice. There are already many investigations for computer-based problem practice, but most of them are focused on the student modeling or practice strategy. However, we believe that the problems as practice material are the basis of problem practice. The abilities of a student model and practice strategy depend on the quantity and quality of prepared problems. From this viewpoint, how to describe problems and how to get the data are key issues to achieve the advanced practice [Hirashima 93; Ritter 98; Arroyo 00; Hirashima 01]. We call this issue "problem-authoring". There are several types of problem-authoring methods. Our current target is to make various problems that can be solved using the same solution method. We call this type of problem-authoring method "solution based problem-authoring". "Problem-authoring" signifies this "solution based problem-authoring" in this paper.

In this paper, a problem-authoring method is proposed and an example of the implementation of the method is described. In the problem-authoring method, a new problem is characterized using differences from the basic problem. In the problem-authoring environment, a user can make a new problem by changing the basic problem. The changes represent the differences between the new problem and the basic problem. The new problem is then characterized by the differences from the basic problem. We call the problem–authoring method "Differential Indexing".

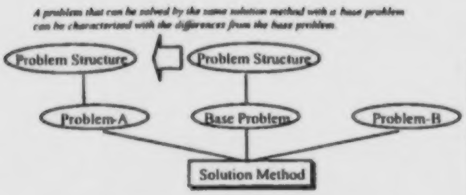
In section 2, a classification of problem-authoring methods from the viewpoint of problem indexing is described. Then, a method of problem indexing, that is, Differential Indexing is explained. A problem-authoring environment as an implementation of Differential Indexing is also described in section 3.

Problem-Authoring

Level of Indexing

In problem-authoring process, a user usually makes problem sentences that are the body of the problem. However, it is difficult for the computer to interpret the problem sentences directly. Giving indexes to the problem and dealing with the indexes as the content of the problem is a useful as well as a popular way. In this paper, we also adopt this approach and propose an indexing method as a problem-authoring method.

Indexing methods are categorized in the following three levels: (1) flag level indexing, (2) keyword level indexing, and (3) problem structure level indexing. In the case of the flag level indexing, each problem has a flag representing a specific number or symbol. The courseware of the problem practice deals with any problems with the flags. In other words, the flag level index is used to identify a problem but doesn't describe the content of the problem. Therefore, problem-authoring and courseware designing cannot be separated. It is then very difficult



A problem that can be solved by the same solution method with a base problem can be characterized with the differences from the base problem.
Problem Structure
Problem Structure
Problem-A
Base Problem
Problem-B
Solution Method

Figure 1: Concept of Differential Indexing.

The number of legs of a crane is two.
The number of legs of a turtle is four.
There are cranes and turtles, 20 in total.
The total number of legs of the cranes and turtles is 48.
How many cranes are there?
How many turtles are there?

Figure 2: Problem-1: Base Problem of Crane-Turtle Method.

(Step1) :The supposed total number of legs when it supposed that there were only cranes.

*(the total number of cranes and turtles) * (the number of legs of a crane) = A*

(Step2):The difference in the above number and actual number of legs.

(the total number of legs of cranes and turtles) -A = B

(Step3): The difference of number of legs when a turtle is substituted to a crane.

(the number of legs of a turtle legs) - (the number of legs of a crane) = C

(Step4): Total difference(Step2) / Individual difference(Step3) is the number of turtles substituted to cranes.

B / C = (the number of turtles)

Figure 3: Crane-Turtle Method

to reuse the problem data with other systems.

In the case of keyword level indexing, indexes of a problem are composed of a set of keywords that describe the content of the problem. In the courseware of the problem practice using the keyword level index, problems that include required keywords are used. Therefore, if the problem author and courseware designer share the meanings of the keywords, the problem authoring and courseware designing can be separated. However, it is often difficult to make the meanings of the keywords clear systematically, because they often depend on the specific system.

If the indexes of a problem include enough information to solve the problem, we call it "problem structure level indexing". To realize such a level of indexing, a problem solving model should be prepared and the indexes should be described based on the model. In order to share the meanings of the indexes, the problem author and courseware designer have to share the model. Although the description ability of the indexes is restricted by the model, the model usually doesn't depend on the specific system and therefore sharing it with the author and the designer is easier. This problem structure level indexing is the target level of this research.

Concept of Differential Indexing

In this research, we give the indexes that describe differences from base problem to a problem. We call the indexing method "Differential Indexing". Figure 1 shows the concept of Differential Indexing. In this method, a combination of a base problem and a solution method is necessary. We call the pair the "Solution Model". This indexing method can then be used to make problems that can be solved using the same solution method with the base problem. For example, if Problem -A can be solved using the same solution method with the base problem, it can be characterized by the difference of problem structure from the base problem. Then, the differences are used as the indexes of the Problem-A. The differences decide the worth of the practical problems, like Problem-A, because all factors a learner has to overcome to master the solution method are included in the differences. Therefore, the index described as the differences is enough from the viewpoint of "solution based problem authoring". This is the concept of Differential Indexing. In the next section, the problem solving model used to describe these differences is explained.

Indexing Method

In Differential Indexing, the following two differences from a base problem can be categorized: (1) an instance difference, and (2) a structure difference. The structure difference is divided as (2a) a structure difference that can be complemented with fact knowledge, and (2b) a structure difference that can be complemented with operational knowledge. In this section, the aforementioned three differences are explained by using the crane-turtle method as an example. The base problem and the calculation procedure of the method are shown in

BEST COPY AVAILABLE

Figure 2 and 3.

Instance Difference

Figure 4 shows Problem-2 that can be solved using the crane-turtle method. In the problem, an octopus corresponds to a crane, and a squid corresponds to a turtle. This problem is different from the base problem in instances, but the problem structure is the same. This is an example of the instance difference. If this problem is difficult for a learner, it speculates the cause of the difficulty is in the instance differences.

Figure 5 shows Problem-3 that also includes the instance difference. In the problem, a boy corresponds to a crane and the score corresponds to the number of legs. Usually, people judge Problem -3 as more difficult than Problem -2. The cause of this distinction is in the quality of the instance changes. To deal with the quality of the changes, in Differential Indexing, a hierarchical structure of concept classes is prepared. The distance in the hierarchical structure from the class that the base problem belongs to describes the quality of the instance changes. When the distance is longer, a problem becomes more difficult.

Structure Difference

If the following two sentences, that is, "the number of legs of an octopus is eight" and "the number of legs of a squid is ten" are missing in Problem-2, there are structure differences between the base problem and this problem. Here, if a student has the knowledge about "the number of legs of an octopus" and "the number of legs of a squid", the differences can be complemented with them. Therefore, we call this type of the structure difference, "structure difference that can be complemented with fact knowledge". If a learner who can solve Problem -2 cannot solve the problem that includes this structure difference, it is estimated that the difficulty for the learner exists in the structure difference. We call this structure difference "the first-order structure difference", and a problem that includes only this type of structure difference, "the first -order problem".

When "the total score of the pupils" is omitted and then "the average score of the pupils" is given in Problem -3, the problem has another type of structure difference. To apply the crane-turtle method to the problem, "the total score of the pupils" is necessary. In this case, "the total score" can be derived by using both "the average score" and "the total number of the pupils". This is the structure difference that can be complemented by operational knowledge. We call this structure difference, "the second-order structure difference", and a problem that includes this type of difference, "the second-order problem". A problem that only includes the instance difference is called "the zeroth-order problem".

In Differential Indexing, the indexes of a new problem are described with instance differences and structure differences. In the problem-authoring environment described in Section 3, the indexes are represented by XML (eXtensible Markup Language) and the problem data can be made and used through the internet.

Problem-Authoring Environment

We have now implemented a problem -authoring environment. The main component is the problem-making editor where a user can make problems. It can also diagnose problems and acquire knowledge for the diagnosis through the problem-making process.

The main task of the problem-making process is to provide indexes for a new problem. Figure 6 is the interface of the problem-making editor. (Currently, only a Japanese version is implemented. Words in the figures were translated into English). The interface is composed of (a) a problem sentences field, (b) a problem-indexing field, and (c) a problem confirmation field. When a user selects a solution method, the base problem of the solution method is given in the problem-indexing field (in this section, a user means a problem author). In the problem-indexing field, each line is corresponding to a basic relation composed of an object, an attribute, and a numerical value. The left-hand column is the statement of the way to give the value. The "given value" is the value that is given in the problem directly. "Not given (fact)" is the value that is not given in the problem, but can be complemented by fact knowledge. "Not given (operational)" is the value that is not given in the problem, but can be derived by operational knowledge. This is the problem structure of the base problem. By changing the concepts or the statements, the problem structure of the new problem is generated. The indexes of the new problem are described as the changes.

The number of legs of an octopus is eight.
The number of legs of a squid is ten.
There are octopuses and squid, 20 in total.
The total number of legs of the octopuses and squid is 180.
How many octopuses are there?
How many squids are there?

Figure 4: Problem-2: An Example of Instance Difference.

There are 40 pupils in the class.
The total score of the test of the pupils is 2760.
The average score of the test of a boy is 65.
The average score of the test of a girl is 75.
How many boys are there?
How many girls are there?

Figure 5: Problem-3: An Example of Instance Difference.

	object	attribute	value
answer	cranes	number	
answer	turtles	number	
given	a crane	number of legs	2
given	a turtle	number of legs	4
given	cranes and turtles	number of legs	
given	cranes and turtles	number	

Figure 6: Interface of Problem-Making Editor.

Concluding Remarks

This paper described a problem-authoring method and a problem-authoring environment where the method was implemented. The environment is composed of Problem-Making Editor, Problem Database and Practice Editor. A user can make problem with the Problem-Making Editor. Problems made in the Problem -Making Editor are saved in Problem Database. In Practice Editor, a user can build a simple problem practice CAI by designing a problem sequence. These components can be accessed through the internet. Evaluation of this problem-authoring environment is our future work.

INTRODUCTION

The U. S. National Science, Technology, Engineering, and Mathematics Education Digital Library (NSDL) does not currently exist except as a vision and goal for the STEM community with initial funding from the National Science Foundation (NSF)—a vision that is different from any existing library today. Currently a set of multiple funded grant projects with formal and informal partnerships among universities, K-12 schools, professional organizations, government agencies, non-profit organizations, and corporations, the library is moving toward realization. When the NSDL opens its virtual doors in fall 2002, it will be the culmination of over a decade of research and collaboration among librarians, technologists, and educators in the public and private sectors (National Research Council, 1998; Wattenberg, 1998; Zia, 2001).

A community that is a special focus for the program is K-12, one that is in many ways a new challenge for the developers who are predominantly from higher education and the research community (National Research Council, 1999). As part of a project funded by the National Science Foundation, TeacherLIB has provided a review of the issues that arise if the library is to positively impact student achievement in K-12 mathematics and science (Hunter, Mardis & Hoffman, 2002).

A VIRTUAL LIBRARY VISION

Critical barriers for digital libraries today are as much human issues as technological ones. Even when good collections are developed, getting them known and used remains problematic in this age of Internet information overload. Today the Internet offers lots of "stuff," but finding the "right stuff" may be difficult or impossible even when it is available (Zia, 2001). This conclusion is reinforced by the research on search engines by Lawrence and Giles, who noted that popular Internet search engines "could be compared to a phone book which is updated irregularly, is biased toward listing more popular information, and has most of the pages ripped out" (Lawrence & Giles, 1999). Further, when confronted by the overwhelming amount of content, learners may not have the experience or basic knowledge to evaluate and use the resources that are found. Some studies of pre-college students have indicated that they spend increased research time looking for materials and less actually reading and analyzing web-based content.

A prime consideration in building digital libraries is ensuring that users needs are met, which implies that one size will not fit all. The NSDL is viewed as having many kinds of resources and services that go beyond the traditional books and journals of brick-and-mortar libraries, with resources including non-textual sources and educational

---

This material is based upon work supported by the National Science Foundation under Grant No. 0085866, TeacherLIB. materials such as lesson plans, curriculum guidelines, and tutorials. "Beyond providing traditional library functions such as the intelligent retrieval of relevant information, indexing and online annotation of resources, and archiving of materials, the digital library will also enable users to access virtual collaborative work areas, hands-on laboratory experiences, tools for analysis and visualization, remote instruments, large databases of real-time or archived data, simulated or virtual environments, and other new capabilities as they emerge" (National Science Foundation, 2000).

While digital libraries have been widely discussed, the NSDL is different because of its focus on education. At workshops in 2000 organized by the current grant recipients (Manduca, McMartin, & Mogk, 2001), educational goals were defined including:

- Provide quality assurance of resources in the collections;
- Enable contextual learning;
- Empower critical literacy skills;
- Support new pedagogical approaches;
- Advance scientific knowledge and understanding;
- Enable inter- and multi-disciplinary educational opportunities;
- Implement the National Science Education Standards (National Research Council, 1996) and related SMET education reform programs;
- Support independent learning;
- Support learning that is active, and that involves inquiry and discovery;
- Foster a sense of excitement about life-long learning;
- Provide access for all;
- Empower users;
- Support communities of scholars.

CHALLENGES IN K-12 DEPLOYMENT

As the NSDL program moves forward, it moves from issues of creating a technical infrastructure to impacting learning in communities with structures and cultures that emerged long before the digital age and are not always well positioned to take advantage of new technologies. In an examination of those issues, researchers for the TeacherLIB project detailed a range of concerns that must be addressed before the digital library can become a primary tool in K-12 classrooms in the United States (Hunter, Mardis, & Hoffman, 2002). These include social, economic, cultural and technical barriers.

Many challenges are well understood as technology enters K-12 schools, including teacher time, training, skills, and attitudes, issues of access to appropriate hardware and software, technical support, and organizational structures that can make it difficult for teaching reforms to take hold. Further, issues of the digital divide may limit the reach of the new library to those who have the most to gain from new teaching tools.

At the same time there are some new challenges that are particular to envisioned library that are emerging as new structures are being tested. The following are not intended to cover all possible issues but to give a sense of some of the emerging issues that have been discussed as the library is moving towards reality.

Accommodating the diverse curriculum requirements of American schools: Despite a decade of developing national standards, each state (and often local district) has revised the standards to meet local concerns and priorities. Students are assessed through state-mandated tests rather than a national testing system, and increasingly curriculum is driven in K-12 schools to raise test scores. Teachers are pushed to adopt learning materials that are tightly aligned with local standards. As a result, learning materials that are not perceived to meet these needs may face a more difficult struggle in adoption. Can a national library find ways to tie in local standards effectively? Some projects are already examining ways to match state standards to library content so that it is customized for each viewer.

Access to the range of potential high-quality content: U.S. schools that receive federal funds for telecommunications (known as the Universal Service Fund or E-rate) are required by federal law to filter content to protect minors from unacceptable content. Studies of these filtering systems have shown that they may block content that is critical for teaching science or mathematics because it covers subjects such as sexually transmitted diseases or references to male or female anatomy. Library developers will need to work with schools and commercial manufacturers of filtering programs to ensure that the rich resources are available to all students.

Personal portals in a protected world: One of the most powerful concepts being developed for the NSDL is the personalized portal. Through customized portals that "recognize" each user, an individual learner has the potential to gain scaffolded assistance in their educational explorations. Under federal laws and regulations, however, the kinds of personal information that may be needed to make such portals highly effective cannot be released by American schools. As a result, tracking mechanisms that could potentially provide support for each learner may not be possible within this protected environment. Developers will need to find creative ways to advance such technologies while ensuring high levels of security for minors.

Incorporating legacy collections: Many excellent collections that are now in use by K-12 that are developed as the result of intensive local efforts or larger national reform projects were never designed to be used in a more structured library effort. These collections may have a mix of high quality materials and underdeveloped experimental materials that never reached conclusion. As teachers demand that their time be maximized so that they are not required to review hundreds of resources to find the right item for the age group and subject they are teaching, these materials may have insufficient metadata to assist teachers in limiting their search. New ways of labeling may be required that go beyond the traditional library catalog to assist users in finding materials that are reviewed and tested. As yet, the methods and data structures for such reviews remain to be developed and tested in real classrooms. Even further away are the tools that will allow such schema to be readily applied to materials that were not developed with such a labeling process in mind. In many cases, the personnel simply does not exist among these K-12 collections to develop high level metadata that may be needed for ready K-12 access.

FUTURES FOR E-LEARNING

Although technical, informational, and organizational challenges remain, NSDL continues to move forward towards its Fall 2002 launch date. The scope of the overall program is providing new hopes for reforming math and science learning for K-12 students. While the challenges are great, the potential continues to motivate the digital library community to develop new methods for deployment that will work well for children and provide new access to high-quality learning.

An Examination of the Elements and Principles of the Visual Design of Web-Interfaces in the Context of Improving Accessibility for Older Adult Users

Charlotte Holland
School of Education Studies
Dublin City University
Ireland
charlotte.holland@dcu.ie

Abstract: This paper introduces elements and principles of visual design, and examines these in the context of designing web interfaces that are accessible to older adult users. It begins by looking at the background to the projected increases in the aged population and the physiological effects of ageing. The discussion continues by reviewing the elements and principles of visual design, and moves forward to focus on the possible impacts of visual impairments on visual interface interpretation. It concludes by outlining the next stages of this work-in-progress and some of the aspirations of this investigation.

Introduction

Improvements in the life expectancy rate has resulted in projections of a massive increase in the number of older adults in society of the near-future. "Thirty years from now, it is estimated that one in four people in the developed world will be aged 65 and over, an increase from one in seven today" (Preston, 1999).

The 1996 Irish Census (Central Statistics Office, 1996) showed that almost 29% of the population were aged between 25 and 44, with a further 11% aged between 45 and 54. By 2026, these two categories of the population will form the older adult community and, when the improved life expectancy rate is taken into account, this older adult community may represent over thirty-five per cent of the total Irish population.

In Ireland, as in many other countries, government and state agencies, (McCall, 2002), commerce and educational institutions are making significant strides in bringing a wide range of services from life events to career choices and leisure options online. The proliferation of information that is now communicated using web technologies in particular demands that all sectors of society gain access and interact with new technologies.

How accessible is this information transmitted using web technologies to older adults? The ageing process can result in diminished vision, hearing, hand-eye co-ordination and psychomotor impairments, (Vanderheiden, 2000). The most common of these physiological changes associated with longevity is the change in vision. "By age 65, most people have lost at least some of their ability to focus; have a reduced field of vision, ability to resolve images, distinguish colours and adapt to changes in light" (The AgeLight Institute, 2000).

The World Wide Web Consortium, W3C, published the Web Content Accessibility Guidelines 1.0, WCAG 1.0, in May 1999 with the aim of explaining how to make web content accessible to people with disabilities. The specification contained fourteen guidelines, (W3C, 1999), that address barriers in web pages which people with physical, visual, hearing and cognitive/neurological disabilities may encounter.

The White Paper published by the Age Light Institute in 2000 focused on maximising usability and accessibility in web-site design for seniors and older Internet users in particular. It highlighted general design elements to make websites more 'senior-friendly', and as such has "raised awareness of design parameters and usability considerations for the increasingly varied demographics and lifestyles of computer users" (The Agelight Institute, 2000).

Physiological Effects of Ageing on Vision

"As one ages, the likelihood of vision loss increases significantly. For those over age 65, one in nine people experience serious vision loss. This rate increases to one in four for those over 85" (Vision Loss Resources, 1997).

During the aging process, the average person will probably experience some of the following eye conditions and resultant vision changes (National Eye Institute, 2001):

- Yellowing of the Lens occurs when the fibres of the lens take on a yellow hue and results in difficulty in contrasting colours, in particular, blue, green or violet.
- Fixed Lens occurs when the lens becomes more rigid and loses its ability to focus on objects that are close. The lens may also become denser and cloudier, which cuts down on the light that is passed through to the retina, resulting in a loss of visual acuity.
- Loss of Pupil Expansion is where the pupil reduces its ability to expand resulting in less light entering the eye. This combined with a dense lens often means that older people need three times more light to see. It results in a loss of ability to adapt to glare, difficulty seeing in the dark and adapting to light changes, hence causing eye-strain or eye fatigue. "Resistance to glare is 2.5 times greater at 20 than at 65" (Flax & Luchterhand, 1995).
- Floaters are condensations of cells in the gel parts of the eye and take the form of tiny spots, specks or strings that float across the field of vision. "Floaters are very common in the elderly, patients with nearsightedness, diabetes and high-blood pressure" (Ohiolions Eye Research, 2000).

In addition to the age-related vision changes discussed above that occur for most older adults, some older adults will experience eye diseases and resultant effects on vision as outlined below (National Institute on Aging, 2002):

- Age-related Macular Degeneration occurs when the central part of the eye dies off creating a black hole or blind spot in the central field of vision. Whilst peripheral or side vision may be maintained, it leads to difficulty in reading, recognising faces or doing 'close-up' work.
- Cataracts results from the clouding of the lens inside the eye, which reduces light entering the eye, and can cause blurring across the entire field of vision.
- Glaucoma and Retinitis Pigmentosa are different diseases but both result in a gradual loss of peripheral vision, leaving a central field of vision or tunnel vision and eventually blindness.
- Diabetic Retinopathy occurs in long-term diabetics where damage can occur to the retina. The blood vessels leak creating large floaters that move across the field of vision.

Therefore, older adults may experience, in addition to eye-strain and eye fatigue, a reduced field of vision, blurred vision, reduced ability to resolve images, reduced colour discrimination, sensitivity to glare, night blindness, a degree of colour blindness and a loss of visual acuity.

How will these physiological changes in vision, brought about by the ageing process, impact perception of and interaction with the visual elements and principles of the web interface? In order to answer this, we first need to establish the constituents of visual design, namely, the elements and principles of visual design.

Elements of Visual Design

The main elements of visual design as described below are texture, form, line, value, colour, space and shape, (Crystal Production Company, 1996):

Texture refers to the simulated surface quality of artwork. *Form* describes the 3-D aspects of objects that take up place. *Lines* can be expressive and suggestive; they can be used to outline the edges of forms or shapes; they can be used to indicate action and physical movement; they can be used to create value and textures. *Value* refers to dark and light, it can be used to develop suitable contrast between foreground and background and to describe form. *Colour* has three properties; hue, value and chroma. The hue is the name of the colour: red, yellow and blue. Colour value refers to the lightness or darkness of the colour. Chroma is the intensity of the colour or the purity of the hue. *Space* can be empty or filled with objects. *Shape* is an area that is contained within an implied line, or is identified because of colour or value changes. Shapes are 2-D, and can be geometric or free-form.

Principles of Visual Design

The principles of visual design below include rhythm, emphasis, contrast, pattern, visual movement and balance (Crystal Production Company, 1996).

Rhythm is the repetition of the visual movement of each of the elements. It can be regular or irregular, staccato(abrupt and change frequently) or progressive(change size whilst moving). *Emphasis* is where the elements are emphasised to achieve dominance or to create a focal area of interest. *Contrast* is where elements are contrasted to achieve dominance. *Pattern* uses the elements in planned or random repetition. They increase visual excitement by enriching surface interest. *Visual Movement* can be used to direct users to focal areas (Vaughan, 1997), such movement can be along lines, edges, shapes and colours. *Balance* refers to the distribution of visual weight in a work and can be either symmetrical or asymmetrical.

Visual Design Considerations for Web Interfaces

Of elemental concern in the visual perception of the visually impaired older adult, would be the use of colour, value, texture and space. These elements would further be enhanced or detracted by the use of rhythm, pattern, emphasis, contrast, visual movement and balance.

For example, think of an interface that uses a font of appropriate size and colour contrast, but has a shadow added for emphasis. How will a visually impaired adult user perceive the 'shadowed' text? Depth perception difficulties may arise?

How about an interface that displays a font that is marginally lighter in colour than the background, will the adult user who has a loss in colour perception be able to perceive the difference? Are low value/contrast colours a good choice in this case?

What would a user with discoloration in the eye fluids and lens (or yellowing) experience when viewing visual elements on a colour 'co-ordinated' web interface? Would the colour contrast/ value still be significant?

What about the placement of the visual elements on the interface, is the amount of white space surrounding the block/s of text large enough, how will this impact on readability of the text for the visually impaired adult user?

Consider the interface that uses geometric textures/pattern in the background, how do these textures affect the contrast or readability of text/ images? Are organic textures/patterns a better option?

Now consider the web interface that incorporates moving text or images, how does the rhythm and/ or movement of these images affect the visually impaired adult user?

Next Stage

The sample questions above are among many questions that are currently under investigation in a review of the visual design of contemporary web interfaces aimed at the adult population in Ireland, tentative findings will be released over the next few months. It is hoped that this investigation into the impact of visual impairments on perception of visual elements and principles of web interfaces may help establish the current state of accessibility of such sites. Furthermore, it is desired that this investigation will raise an awareness of the need for more detailed research on all aspects of web interface design for an ageing population.

"Bringing Stars into the Classroom"- A unique model for virtual courses

Yona Holtzman-Benshalom, Yoav Yair and Dafna Raviv
TAMID Project, The Open University of Israel, Tel-Aviv, Israel

Astronomy teaching is a challenge even to the veteran science teacher. It is a dynamic and changing field of science, where the constant flow of new discoveries require rapid and continuous updating of the study materials. Alongside the enormous popularity of astronomy and space science amongst children, are found many misconceptions and misinformation about their basic facts. Children may conceive explanations for natural astronomical phenomena from popular resources such as science fiction movies, video games, television series and informal internet resources (mostly on UFOs and aliens). There is an extensive literature on misconceptions in astronomy and their origins, which includes pedagogical ideas and recommendations of how to avoid them, and the most suitable teaching strategies at each age. Since astronomy was introduced into the science curriculum in Israel 6 years ago, there has been an intensive effort to train teachers in this field.

The course we describe here was designed for junior-high school science teachers, who have not received any formal training in astronomy and who have never before taught the subject in their classes. It was a 12-weeks hybrid course consisting of a few face-to-face meetings, independent -learning, and extensive on-line activities, using the Open University's Opus LMS (an internally developed, non-commercial, Hebrew-based set of web tools).

Initially, the course was focused on teaching the subject matter and on forming a active learning community. This involved educating the participants in the use of the course web-site which forms the central axis of their learning, by means of ongoing mentoring and moderating by the course tutors in the forums. The method of using specific repetitive activities such as "Ask the expert" or "What's up in the sky" have helped teachers overcome their initial shyness and lack of confidence, caused by their feeling of "not knowing anything in astronomy". By giving legitimacy to their questions, a shared resource of answers was rapidly built, shared and later used by the teachers themselves as an extensive data-base. The constant dialog about current celestial events (we were treated to a beautiful comet and a rare planetary conjunction) generated the enthusiasm and motivation to report observations, and teachers soon began to harvest updated astronomy news from the plethora of web resources and the popular media in general. Additionally, teachers were asked to come up with lesson plans, suggestions for overcoming hurdles in teaching and to respond to and discuss the products of their peers

The teachers became "advocates of astronomy" among their colleagues and soon started teaching the subject in their classes. They presented the feedback and questions of their pupils in the course online forums, and these were discussed and shared amongst the participants. Suggestions, comments and even compliments from their colleagues created a positive learning atmosphere. Consistent accompaniment of the course by subject experts has greatly eased the burden of first-time teaching processes and experiences (of astronomy), and the on-line mentoring was the attribute most noted by the teachers as being central and essential to fulfilling their expectations of the course.

A self-generated model of "learning on-line while teaching in the field" can be successfully implemented in content area courses other than Astronomy, as long as constant concern and care are given in balancing the amounts of basic subject material and didactic activities, with implementation tools and motivating assignments . Essentially, in the Astronomy field, that is what the teachers really need and may use , in order to bring the stars from heaven above down into their classrooms.

"Bringing Stars into the Classroom":

(A Unique Model for Virtual Courses for Science Teachers)

TAMID Project, The Open University of Israel, Tel-Aviv, Israel

Astronomy teaching is a challenge even to veteran science teachers. It is a dynamic and changing field of science, with a constant flow of new discoveries that require rapid updates to the study materials. The enormous popularity of astronomy and space science among children is too often mixed with conceptual errors and misinformation about the basic facts in these sciences. Children may conceive explanations for the natural astronomical phenomena from popular resources such as science fiction movies, video games, television series and informal internet resources (mostly on UFOs and aliens). There is an extensive literature about misconceptions in astronomy and their origins, with ideas and recommendations of what pedagogy should be used in order to overcome them, and what teaching strategies are best for each age. Since the introduction of astronomy into the science curriculum in Israel 6 years ago, there has been an intensive effort to train teachers in this field.

The course we describe here was designed for junior-high school science teachers, who have not received any formal training in astronomy and who have never before taught the subject in their classes. It was a 12-weeks hybrid course which consisted of a small number of face-to-face meetings, self-learning studies, and extensive on-line activities, using the Open University's Opus LMS (an internally developed, non-commercial, Hebrew-based set of web tools). Initially, the course was focused on teaching the subject matter and on forming a vivid learning community. This involved educating the participants to the use of the course web-site as the center axis for their learning, through constantly mentoring and moderating by the course tutors. Focused and regularly repeated activities such as "Ask the expert" or "What's up in the sky" have helped teachers overcome their shyness and lack of confidence, expressed by the feeling of "not knowing anything in astronomy". By giving legitimacy to their questions, a shared resource of answers was rapidly built, shared and later used by the teachers themselves as an extensive data-base.. The constant dialogue about current celestial events (we were treated to a beautiful comet and a rare planetary conjunction) created enthusiasm and motivation for reporting observations accordingly, and teachers soon began to harvest updated astronomy news from the plethora of web resources and the popular media in general. Additionally, teachers were asked to come up with lesson plans, suggestions to overcome hurdles in teaching and to mutually discuss the products of their peers.

The teachers became "advocates of astronomy" among their schoolmates and soon started teaching the subject in their classes. They brought the feedbacks and questions of their pupils into the online forums, and these were discussed and shared among the participants. Suggestions, comments and even compliments from their colleagues created a positive learning atmosphere. The constant escort by subject experts has greatly eased the burden of first-time teaching processes and experiences (of astronomy), and the on-line mentoring was the attribute most noted by the teachers as central and essential to fulfilling their expectations of the course.

A self-generated model of "learning on-line while teaching in the field" can be a successfully carried out for both Astronomy courses and any other subject matter courses proposed, as long as constant concern and care are given to balancing the amounts of basic subject material and didactic activities, with implementation tools and motivating assignments . Essentially, in astronomy teaching that is what the teachers really need and may use, in order to bring the stars from heaven above down into their classrooms.

An Empirical Study of the Learning Motivation, Satisfaction, and Effectiveness among Web-based Learners in Taiwan

ABSTRACT The present study investigated the relationships among e-learners' behaviors in terms of their motivation, satisfaction, and effectiveness. 139 college undergraduates enrolled in a business course offered in an internet learning environment called the VICAS System voluntarily at the National Taiwan University. The system was developed in house and contains six major parts, including course materials, multi-media capability, interactive testing, discussion forum, message, and personal notes. The findings indicated that there displayed strong correlations among the learners' motivation, their learning satisfaction, and their learning effectiveness. In addition, "richness" of the system was singled out as a critical factor for e-learning.

INTRODUCTION

E-learning may become one of the most popular and cost-effective ways of learning with traditional students as well as lifelong learners. This is because with e-learning, the "same place," the "same time" and the "same pace" type of learning is a way of the past. The "learner" is in full control over the time and place of his learning as well as the pace of the learning. She may at a click decide to joint a virtual community for a collaborative learning. Over 70 million people, according to Cisco, were learning on the internet as of 2001. One day, training of all kinds in this world will be available on the Web. In a global society, where knowledge is being viewed as a source of nation's health as well as its economic competitiveness, how to offer the best possible education or training and how to take advantage of lifelong learning opportunities become crucial.

Cooperative (collaborative) learning is one of the strong points in advocating e-learning. In the past, collaborative learning was not widely accepted because academic excellence was defined by individual achievement via competition. However, collaborative learning is now back on campus (Johnson, Johnson & Smith 1998; Stein & Hurd, 2000). It is believed that e-learning is most effective in collaborative means via learning communities (Alavi, 1994; Azmitia, 1988; Dillenbourg, et al, 1994; Goeller, 1998).

E-learning is one form of the distance learning and can deliver instructional materials to those who would like to learn on the internet. There are lots advantages of using internet for instruction, learning or training. For one, it is not restricted by the time and place of learning. In other words, it is available anywhere and anytime. For another, learners have the full control of the learning process in terms of the speed, contents, subjects, place and time. For yet another, both the learning and the instruction can be interactive. Besides, e-learning may deliver accessibility, opportunity, and accountability.

As Leidner and Jarvenpaa (1998) indicated that learning would be best achieved through an active involvement. Other researchers (Alavi, et al, 1995) also stated that for learning to be successful, course designing must be in such a way to encourage active student involvement beyond passive note taking. Murray (1938) was one of the first to call for the attention to the need of achievement as the desire to perform things well, to accept difficult challenges, to overcome obstacles, to excel in something, or to surpass others. As a result, many researchers (Asbury, 1974; Atkins & Raynor, 1974; Clarke, 1973; Griffore & Lewis, 1978; Matthews & Chan, 1980; Waters & Waters, 1986) attempted to develop achievement motivation instruments. Chiu's (1997) the School Achievement Motivation Rating Scale was also one of

BEST COPY AVAILABLE

these attempts. Pintrich, et al (1991) investigated learning motivation strategies to compare private and public thoughts and behaviors that might contribute to successful learning.

"Motivation theories are built on a set of assumptions about the nature of people and about the factors that give inpetus to action (Deci & Ryan, 1985, p. 3)" Most psychologists like to use the word of "motivation" to describe the process to deal with four things when it comes to learning and education. Those four things are used to 1) arouse and instigate behavior; 2) offer direction and purpose to behavior; 3) allow continually behavior to persist; and 4) lead to choosing or preferring a particular behavior (Wlodkowski, 1985).

There are in essence two types of motivation, namely, the extrinsic motivation, which was established in 1971 and was based on findings of numerous researchers in psychology, according to Skinner (1953), and the intrinsic motivation, which was first advanced by Deci (1971). The former refers to choose an activity for no compelling reason, beyond the satisfaction derived from the activity itself, while the latter deals with motivation to engage in an activity as a means to an end. Individuals who are extrinsically motivated work on tasks because they believe that participation will result in desirable outcomes, such as reward, teacher praise, or avoidance of punishment. It is the intrinsic motivation that this study is intended to focus on.

Deci in 1971 argued for the first time that extrinsic rewards not only could not provide any positive motivation, but also could undermine the intrinsic motivation in some activities because those activities could be intrinsically motivated by their very own nature. His general findings were later replicated by Lepper, Greene, and Nisbett (1973). Nevertheless, this school of thoughts has been continuously considered as the focus of controversy by researchers and practitioners. While the debate continues, this line of thinking has been expanded and can now be classified into three major types of theories. They are motivational theories (Deci, 1971, Deci & Ryan, 1980, 1985, 1991; Ryan, 1982, 1995), behavioral or cognative theories (Scott, 1975; Dickinson, 1989; Flora, 1990; Carton, 1996; Eisenberg & Cameron, 1996), and attributional theories (Kruglanski, 1975; Lepper, 1981; Lepper, Sagoysky, Dafoe, & Greene, 1982; Higgins & Trope, 1990).

Under motivational approaches, rewards are considered to have conflict effects (Deci, Koestner, Ryan ,1999). On the one hand, it is considered as controlling, meaning it may thwart satisfaction of the need for autonomy, and it may also, on the other, be considered as informational, thus offering satisfaction of the need for competence. That is why additional factors have to be added in order to be able to predict the likely effects of such rewards. Those factors may include, but are not lmited to, reward contingencies (Ryan et al, 1983), verbal rewards (Deci, 1971; Ryan, 1982), Symbolic cue value (Harackiewicz, 1979; Harackiewicz, Manaderlink, & Sansone, 1984), and interpersonal contexts (Ryan, 1982 ; Deci, Nezlek, & Sheinman, 1981; Deci, Connell, & Ryan, 1989; Deci &Ryan, 1991; Ryan 1995).

The users' behavior and the effectiveness of e-learning will always be one of the most important considerations in the success of the learning system. However, very few, if any, efforts have been devoted to the understanding of the application portion of the Web-based learning systems and environments despite the fact that substantial efforts have been devoted to the development and design of those teaching/learning systems and their infrastructure. Basically, we know very little about the e-learners and their behavior. This is especially the case in Taiwan. Besides, mobile learning is expected to be the next wave in online education, understanding the types of contents and the behavior of learners will help e-learning instructors, instructional developers, and administrators, if not the system designers, to take the challenges that wireless e-learning technologies will bring in the very near future.

The present research was designed primarily to examine the relationships between the learning effectiveness and the motivation as well the satisfaction among Web based learners in Taiwan. More specifically, the study was intended:

1. to assess the relationships between the learning motivation and the learning satisfaction among e-learners;
2. to evaluate the relationships between the learning motivation and the learning effectiveness among Web-based learners; and
3. to investigate the relationships between the learning satisfaction and the learning effectiveness among internet-based learners;

RESEARCH METHODOLOGY

The Learning Environment - the VICAS System.

The system was developed by Prof. Ming Chou Hong of the National Taiwan University for learning/training on the internet and has been in use for several years now. It basically contains six major parts, including course materials, multi-media capability, interactive testing, discussion forum, message, and personal notes. The system has the following features: asynchronization, multi-direction, individualization, and self-monitoring.

Subjects.

The sample consisted of 139 undergraduates (51 males) at the National Taiwan University who enrolled voluntarily in an "Introduction to Management" internet course. Of the total, 98 were business majors and the other 41 were none-business majors. 67 subjects were upper-level students and the other 72 were either freshmen or sophomores.

Instruments

The study utilized three instruments. They included the learning motivation scale, the satisfaction questionnaire, and the learning effectiveness scale.

The learning motivation scale was developed by Pan (1997) for his master's thesis and has been used in a number of occasions in Taiwan. They were totally 12 items and scored on a 5point Likert scale with 1 being not influenced at all and 5 being very influenced. Cronbach's alphas for the 12-item in this sample ranged from 0.8131 to 0.8540.

The learning satisfaction questionnaire was developed after an extensive evaluation of five different scales (Wu, 1992; Cheng, 1995; Lin, 1997; Shiao, 1998; Cooper and Bradshwaw 1999). The instrument had 16 items. The first 12 items were related to specific questions, such as the interconnectivity of the system, the interactions between the instructor and the students, the way the information was shared, the richness of the course materials, the way the final grade was assessed, the instructor's general attitudes toward e-instruction, etc. The other four items were to evaluate the overall satisfaction in the learning performance, the course quality, the learning environment, and the instructional method. They were also scored on a 5-point Likert scale with one being not satisfied at all and 5 being most satisfied. The Fishbein's Satisfaction Model was adopted here to accommodate the use of the learning satisfaction question. More specifically, subjects were asked about their learning satisfaction in terms of their anticipated satisfaction level and the actual satisfaction level. Cronbach's coefficients for the 16-item scale were 0.8613 for the anticipated satisfaction level and 0.8823 for the actual satisfaction level.

The third instrument modified Pan's (1999) Learning Effectiveness Scale to come up with 10 items. The scale was to measure the domain knowledge and concept, the abilities of decision-making, thinking, analytic, and language expression, interpersonal relations, communication skills, negotiation skills, collaborativeness, and the overall learning performance. It was based upon a three-point scale with one being learned a lot and three being learned very little and two being the neutral one.

Procedure.

At the outset of the semester when students were gathered face-to-face in their very first class, they were explained about the study and were asked to provide some general background information, including sex, major, the class year, and prior experience with computers, etc.

When the students gathered again face-to-face for the last class of the semester, they were administered the learning motivation scale, the learning satisfaction questionnaire, and the learning effectiveness instrument. In addition, during the course of the semester, students' participation in the discussion forum of the VICAS were monitored and recorded automatically by the VICAS system via its self-monitoring feature.

RESULTS

The 12-item learning motivation scale and the 9item learning effectiveness questionnaire (not counting the overall performance item) were factor analyzed, respectively. The former generated three separate factors, whereas the latter came up with two distinguished factors.

The three learning motivation factors were: 1) learning flexibility, which included six items and explained 27.82% of the variance; 2) richness of contents, which consisted of three items and had a 24.75% of variance explained; and 3) lack of pressure in learning, which was composed of three items and was able to explain 17.69% of the variance. Collectively, the three factors explained 70.26% of the total variance.

The two factors derived from the learning effectiveness questionnaire were: 1) socialization, which had five items included and explained 29.52% of the variance; and 2) ability, which consisted of four items and was able to explain 27.99% of the variance. Together, they were able to explain 52.51% of the total variance.

Satisfaction on	Flexibility	Richness	Pressure	Socialization	Ability
Learning outcomes	0.245**	0.311**	-0.064	0.347**	0.387**
Instruction Quality	0.207**	0.366**	-0.161*	0.303**	0.391**
Learning Environment	0.171*	0.235**	-0.074	0.231**	0.256**
Instruction Style	0.033	0.300**	-0.013	0.218**	0.229**

**p<0.01 *p<0.05

Table 1 Pearson Correlation Analysis

Results of a Pearson correlation analysis between the three-factor learning motivation and the two-factor learning effectiveness indicated that a strongly positive correlation (r=.43, p<.01) existed between "richness" and "ability" and that "flexibility" was weakly correlated to "socialization" (r=.196, p<0.05) and moderately correlated to "ability" (r=.357, p<.01). "Pressure" was not found to be statistically correlated to either "socialization" or "ability."

Table 1 presents the results of a Pearson correlation analysis between the learning satisfaction of the Fishbein model in terms of the last four items, namely the overall satisfaction on the learning effectiveness, the instruction quality, the learning environment, and the instruction style and the three-factor learning motivation and the two-factor learning effectiveness.

SUMMARY

Based upon the findings presented above, it was clear that there were positive correlations between the learning motivation and the learning effectiveness, between the learning motivation and the learning satisfaction, and between the learning satisfaction and the learning effectiveness, respectively.

A number of implications for the findings may be discussed here. First, among the three factors of the learning motivation, the richness was found to be positively and strongly correlated with all four factors of the learning satisfaction, as well as the ability factor of the learning effectiveness. In other words, for learners to be satisfied with the overall learning performance, instruction quality, learning environment, and instruction style, there should be enough information sharing; the contents should be rich enough, and the instructor should have a different teaching style and attitude toward e-learning than the traditional face-to-face learning.

Second, since all four learning satisfaction factors were found to be strongly and positively interrelated to the two learning effectiveness factors, the implications were simple and straightforward. Learners were not satisfied of the learning experience unless the system provided an opportunity for them to improve their abilities in decision-making, thinking, analytic, and/or the domain knowledge and concept, collectively referred to as the "ability," as well as their skills in interpersonal relations, communication, negotiation, language expression, and collaborativeness, classified together as "socialization."

Third, the strong correlations exhibited between the ability factor of the learning effectiveness and the lack of any strong correlations, positively or negatively, between the socialization factor of the learning effectives and the three learning motivation factors could only be interpreted one way. Students signed up for the course primarily to enhance their "ability" factor, not to strengthen their "socialization" factor, which was secondary in their learning objectives in this course. Since the system did help them achieve their primary goal, i.e., to enhance their "abilities," and that is why they were satisfied.

Finally, the fact that the pressure factor of the learning motivation was found to be not correlated to either the four satisfaction factors or the two learning effectiveness factors was not surprising and was understandable. This is because the learning was supposed to be taking place at any time, any place, and any pace. We were not surprised that "pressure" was not found to be a critical factor at all.

Instructional Design, On-Line Classrooms, and Disability

Abstract:

Brief Paper: This brief paper will provide instructional designers with practical suggestions for assisting students with disabilities in college classrooms. Furthermore, it will examine the similarities and differences between the Americans with Disabilities Act (ADA), Section 504 and 508 of the Rehabilitation Act, and these laws affect on instructional design. Included in the brief paper will be suggestions for instructional designers when designing an on-line or web-based class.

Description:

Since the first FTP file was sent circa 1991, the United States and many other countries of the world have been investigating new ways to send information over the realm of the World Wide Web. Many persons can easily send E-mail, perform a Web Search, and design Web pages using a multitude of software products. Universities have begun to explore ways to utilize the World Wide Web to educate and inform their students.

For students at college and universities campuses the use of the World Wide Web by professors is becoming common practice; professors have homepages where students can view syllabi, download readings, and see adjustments to the class schedule. Another example of instructors integrating of technology into classrooms is a class list-server. List serves are mailing lists used by all students in a particular class to post and send information relating to class material. Some instructors require all students participate in discussion on the list-serve for part of their overall course grade. Also, some professors do not collect papers in class anymore; they require the students to submit the papers using email attachments instead. A final example of how technology is being integrated into college and universities course are on-line classes that been developed to allow students to be at a distance and attend classes. Typically these classes utilize software as classroom management tools and include the following areas: discussion posting boards, file exchanges, email applications, course readings posted to the internet, uploaded power point presentation.

These above examples demonstrate how technology is being integrated into higher education. If the information age continues to grow exponentially, the future use of the World Wide Web as an informational and educational tool can be endless for college students. For most students, and professors, this technological integration has made their life simpler; attending classes without leaving the house, getting another copy of a syllabus without visiting the professor, having students view a video tape shown in class, or a web-cast of a lecture they had missed. Yet, for some students the advancement of technologies in the classrooms, either virtual or traditional, has caused distress. Disabled students sometimes have difficulty with the new technologies professors are using in their classrooms to present their course material. Difficulties can stem from not being able to read power point presentations professors project onto a screen, not being able to hear a video playing in a class, and not being able to comprehend information that is presented in large chucks on a computer screen.

Today, there are more students with documented disabilities in higher education than ever before -- 140,142 freshmen reported having a disability in 1996 which represents over 9% of all freshmen (HEATH Resource Center, 1998), as compared with only 2.6% in 1978 (HEATH Resource Center, 1995). The growth in the number of students with learning disabilities has created a new challenge to professors and colleges. Over the years, there has been considerable resistance by professors to alter the way they instruct, particularly if such alteration were to accommodate a student with a mental, as compared to a physical, disability. Many professors prefer that all students meet the same set of requirements, within the same time period, and in the same way, and are ill-prepared either to adapt their instruction to address the individual needs of students or to identify appropriate, fair, and reasonable accommodations (Thomas, 2000). This situation can be improved by the assistance of a university's Student Disability Services (SDS), or similar unit. However, such units often are inadequately funded, given the growth in the number of students requesting accommodation, and seldom have experts on staff who are knowledgeable about the wide range of disabilities that colleges are now attempting to accommodate (Thomas, 2000).

The term disability was modified in 1990, and is broadly defined by congress as "a term that should be used to describe conditions such as perceptual handicaps, brain injury, minimal brain dysfunction, dyslexia and developmental aphasia." Furthermore, Congress has defined a qualified handicapped persons as "an individual with a disability who, with or without reasonable modifications to rules, policies or practices, the removal of architectural, communication or transpiration barriers, or the provision of auxiliary aids, and services meets the essential eligibility requirements for the receipt of services or the participation in programs or activities provided by a public entity." These definitions allow universities to determine if a disabled person is a qualified handicapped person, and if they are, the university must provide accommodations to qualified persons. Thus, these items an instructional designer should become aware of to ensure the materials used in classrooms accommodate disabled students as defined by the law.

The Americans with Disabilities Act (ADA) of 1990, Section 504 of the and Section 508 of the Rehabilitation Act, are laws that exist to protect disabled persons from being discriminated against, and to assure that persons with disabilities are provided with reasonable and proper accommodations. A common theme for each of these laws is they were created, and have been modified, to protect persons with disabilities. Even with this common goal, these laws do have several differences that will be highlighted during the discussion. For example, ADA is designed as an umbrella law, and all United States private and public agencies must comply with the rules and regulation of ADA. The provisions outlined in section 504 only apply to federal agencies and private agencies that accept federal funding (29 U.S.C. § 794(a)). An example of a private institution required to comply with section 504 is a research university that accepts National Science Foundation grants. Finally, section 508 compliance has only been set for federal websites, an example would be the National Aeronautic and Space Administration website.

The main goal of ADA, 504, and 508 are to provide disabled persons with reasonable accommodations and allow them to function at, or near, the same level of non-disabled persons. Currently, the interpretations of these laws intertwine with the moral obligations of society, and form a 'gray area'. In terms of an on-line environment, the moral issue of knowing the University must provide reasonable accommodations for disabled students enrolled in programs the University offers, yet there are no litigations which state technology used outside or during of a face to face is required to be assessable to students. Thus, an interpretation of the gray area can be "it has not been shown that not providing accommodations for disabled students who take classes with technological components is in violation of the law, thus we are doing nothing wrong."

In the context of this brief paper, technology will be defined as materials and devices used by the instructor that goes beyond the traditional lecture. Thus, this brief paper will examine how to modify advanced technology to ensure disabled students are provided the same learning opportunities as non-disabled students. Advanced technology would be considered data posted to websites, projected computer images, on-line classrooms, web-based learning, computer programming software, and list-serves.

The concentration of the brief paper will focus on advanced technology and the considerations instructional designers need to developing course that involves those types of technology. There are solutions, which fit these laws that instructional designers can utilize when technology is incorporated into learning environments to assist student who are visually impaired students, hearing impaired students, and students who have language-processing disorders. For example, when posting a reading to a class website, either in an on-line classroom or a traditional classroom, ensure that the information can be printed in Braille, if not add the proper HTML code to ensure students who are visually disabled can read the information. Another example would be to have all Power Point slides available in printable format for students prior to discussions. This would allow students with disabilities to have a copy of the material in front of them in a format in which they can follow along with the classroom discussion.

Instructional designers need knowledge of disability law so they are able to consider those aspects when designing courses that involve advanced technology. Furthermore, instructional designers need to have knowledge of what should be done to help disabled students in higher education classrooms. These two components will be the start of better instructional design that allows disabled students to excel in college classrooms.

The Value of Community Building in an Online Classroom

Debbie Hu

Higher education is changing. The method for education has begun to shift from traditional classroom delivery to at home delivery; better known as online learning. This paper explores changes occurring in the higher education system in relationship to online learning and community building. Many persons involved in traditional classes can have an easier time forming a community of learners among themselves and their professors. Yet, in online classes, variables such as proximity of students can cause difficulty in building community. If an online classroom lacks community it is more prone to students' failing, conflict, problems, frustration for both students and faculty (Lindner 2002). This paper explores some of the problems and solutions for building an online community, and the positive effects community can have on both the students and faculty in online classes.

The reality of online education is that it favors a transition from traditional notions of academic community toward a much narrower, transactions-based model; which is defined as the psychological and communications space between learners and instructors (Moore as sited in Rovai, 2002). Transactional distance is relative and different for each person. Thus, the pedagogy of faculty members in a distance education course needs to change from a teacher-centered approach to being student-centered (Strain, 1987; Beaudoin, 1990; 1998; Berge, 1998). In traditional higher education, a "community of scholars" was a place where the student was mentored as an apprentice and eventually became a co- investigator in research and creative activity. Though, from the student's perspective, the social and physical distance of online education seems to make students need clear, precise, objectives-oriented curricula which may represent a narrowing of education, and may make them unlikely candidates for collegial work on faculty research projects (Online Classrooms 1999). In 1997, T.H. Murphy noted that the instructional effectiveness of distance education is comparable to that delivered on campus. For distance education programs to be successful they must provide "for appropriate and sufficient synchronous and asynchronous interaction between faculty and students and among students" (Murphy, 1997, p. 8).

An obstacle for students in online classes is the physical separation of the students. Separation has a tendency to reduce the sense of community, giving rise to feelings of disconnection (Kerka 1996), isolation, distraction, and lack of personal attention (Edelstein 2002). This could affect student persistence in distance education courses or programs. Tinto (1993) emphasized the importance of community and theorized that students will increase their levels of satisfaction and the likelihood of persisting in a college program if they feel involved and develop relationships with other members of the learning community. The importance of community is supported by empirical research. Wehlage, Rutter and Smith (1989) found that traditional schools with exemplary dropout-prevention programs devoted considerable attention to overcoming the barriers that prevented students from connecting with the school and to developing a sense of belonging, membership, and engagement. The key finding of their report is that effective schools provide students with a supportive community. Finally, Ashar and Skenes (1993) discovered that learning alone appeared strong enough to attract adults to the program, but not to retain them.

Research provides evidence that strong feelings of community may not only increase persistence in courses, but may also increase the flow of information among all learners, availability of support, commitment to group goals, cooperation among members, and satisfaction with group efforts (Rovai 2002). Additionally, learners benefit from community membership by experiencing a greater sense of well being and by having an agreeable set of individuals to call on for support when needed (Rovai 2002).

It is important to clearly state what community means within the context of this paper. We will define community as: a group of people who are socially interdependent, who participate together in discussion and decision making, and who share certain practices that both define the community and are nurtured by the community. Furthermore, community is an environment in which people act in a cohesive manner, continually reflecting on the work of the group while always respecting the differences individual members bring to the group (Rovai 2002). Yet, an online education community can be viewed as what people do together, rather than where or through what means they do them, community becomes separated from geography, physical neighborhoods, and campuses (Wellman, 1999). Advocates of online education argue that an academic community of scholars could be enhanced through technology. Palloff hypothesized that in principle it is possible to maintain and extend values such as mentoring and co-investigation by means of telecommunications.

There are many advantages to creating a sense of community for the online student. This paper will discuss three advantages. First, students who are engaged in collaborative activities are more likely participate within an online community. For example, online discussions within small groups or learning sets offers a powerful environment for adult learning as it enables members to reflect on each other's experience and to engage in a collaborative tasks. In such groups there is likely to be a high sense of presence and a growing sense of community (Hammond 2000). Furthermore, Royal and Rossi (1996) suggest that learners' sense of community is related to their engagement in school activities, with students who have a higher sense of community being less likely to experience class cutting behavior or thoughts of dropping out of school and more likely to report feeling bad when unprepared for classes.

Second, students who have support are more likely to complete their online course and contribute to the online community. Aviv (2000) states that the supportive interaction process occurs when every member helps each other, gives feedback on processing, reflects on the effectiveness of the community, and advocates effort.

Finally, students who participate in online communities will be more receptive to other academic points of view. For example, Hammond's (2000) research on online discussion forums indicated students using community forums keep an open mind on the value of different types of knowledge, take a critical stance to theoretical knowledge, reflect and seek dialogue and debate with others in the community. These discussions can promote and support participation among students in the online class.

We explored online communities to help students become empowered to build online relationships with other participants in the learning environment. This paper examined three community building activities. First, using collaborative activities such as online discussions to increase a sense of community among students. Second, students gaining support from the community to increase interaction among students thus decreasing the student failure rate. Finally, using forums as a mean to support knowledge perspective taking among students.

On-line Simulations for Health Care Providers

Introduction

This paper will describe the development and implementation of interactive on-line continuing education modules for health care providers. The interactive framework, extensive use of links, pre- and post-testing, and evaluation of outcomes will be featured.

The Internet has become a source for health related continuing education. However, continuing education for health professionals on the Internet must be critically evaluated by the user. Many of these offerings consist of reproduced journal articles or other text-based content. Some of the sites provide few links and offer little or no interactivity.

To address the need for quality continuing education of health care providers, on-line modules were developed as part of a grant-funded nurse practitioner learning project. The feasibility of on-line learning for health professions included the results of a nurse practitioner (n=187) survey of computer availability and skills, topic preference, and their potential for taking on-line continuing education. More than 80% of the respondents had Internet access, and 71% had basic Internet skills. The majority of the respondents indicated their computer met the minimum standards to access an on-line course. Fifty percent of the respondents were very interested in taking an on-line continuing education course. Although the modules were designed from the nurse practitioner data, the modules are appropriate for physicians, physician-assistants, and other allied health professionals.

Designing the Modules

Two modules were designed to be interactive, realistic, self-study simulations that closely resemble clinical practice. "Acute Low Back Pain," and "Common Dermatological Problems in Primary Care" were selected as the topics for development. A preview of the modules is available at http://www.nursing.twsu.edu/clp. This preview was designed to allow learners to explore the modules prior to registration.

The development of the learning materials includes identification of learning objectives, pre-test and post-test construction, extensive search of the Web for related sites, and development of a comprehensive bibliography for further study. In order to establish communication with the learners, the instructors include a brief biographical sketch with photographs. E-mail links for each instructor are provided. An optional area is provided for learners to input information about them and practice as well as questions and comments about the continuing education modules. This is an attempt to establish a learning community for potential communication with one another and the instructors. A "help" section is available for the students who may have technical problems with the program. This link is on-line directly to the educational specialist who assisted with the development of the modules. Following the construction of the modules, each module was submitted to a panel of expert reviewers. Revisions were made based on the expert reviewers' evaluation of the modules.

Learners are guided through the process from registration to completion with on-line submission of the post-test. The course overview presents the learning objectives, the instructors biographies, the module bibliography and related sites, and then explains the structure of the modules. The learner links to the on-line registration process which provides verification of credentials for awarding of continuing education credit. In addition, the registration questionnaire contains additional demographic information and on-line education preferences. The pre-test is automatically graded and the learners immediately receive their scores. The authors elected not to share the answers of the pre-test with the learners until completion of the post-test.

The learner is then directed to begin the case studies. The dermatology module presents 25 brief patient scenarios with presenting history and an image of the condition. The learner is asked to submit the diagnosis and receives immediate feedback. Links are provided for management, additional images, and patient information for each dermatologic condition. "Acute Low Back Pain" contains two extensive, interactive patient case simulations that take the learner through the assessment, diagnosis, and management of the low back pain patient in primary care. Following completion of the case simulations, the learner completes the post-test and electronically submits the answers. The learner must pass with an 80% rate in order to earn their continuing education credit. The modules have been further developed for academic graduate credit ranging from one to three credit hours.

Evaluation

The survey information obtained from the registration submission help to determine a demographic profile of users and motivation for on-line education. To date, 50 learners have completed the modules with others currently enrolled. All learners are Registered Nurses, ranging in age from 25 to 59 years, with learners residing across the United States and internationally. A broad range of nursing specialties are represented including staff nurses, graduate students, directors of nursing, clinical nurse specialists and nurse practitioners. Analysis of data reveals significant differences between the pre-test and post-test knowledge scores.

Learner comments are submitted electronically through an evaluation form and are reviewed for attitudes toward on-line continuing education, satisfaction with the completed module, and the potential for further use. Learners evaluated the modules as innovative, time saving, convenient, available, and economical. Learners particularly liked the case study approach, use of graphics, and the extensive links to other quality web sites. These comments provide feedback for revision of the current modules and future development of additional modules. Outcome data are currently being collected online and will be analyzed for efficacy of this delivery system for continuing education. These data will be analyzed and presented.

Conclusions

Competency-based learning is a preferred method in advanced practice nursing education. Through the use of interactive case studies, we were able to offer time pressed health professionals opportunities for continuing education. The future of on-line continuing health education is dependent on well-structured, interactive, and challenging programs as well as the accessibility and the skill of the user.

Web-Based Instruction—Its Impact on Higher Education

Pei-Wen Nicole Huang

Abstract: A review of the literature and related research concentrates on the area of Web-based instruction is presented in this paper. An overview of Web-based instruction, including its impact on the higher education learning environment, emerging roles for instructors, synchronous and asynchronous learning environments, and creating learning communities are presented in the section.

Introduction

A review of the literature and related research concentrates on the area of Web-based instruction are presented in this paper. An overview of Web-based instruction, including its impact on the higher education learning environment, emerging roles for instructors, synchronous and asynchronous learning environments, and creating learning communities are presented in this section.

Impact on Higher Education Learning Environments

Web-based instruction (WBI) is defined as an innovative approach for delivering instruction to a remote audience using the World Wide Web as the instructional delivery.system (Khan, 1997). It has been used not only in exclusive distance programs but also in supporting face-to-face traditional classroom instruction. Angulo & Bruce (1999), stated in Innovative Higher Education that in 1996 the University of Georgia engaged WBI to supplement their traditional course offerings. Numerous other colleges and universities, such as the University of Colorado at Denver, the University of California system, State University of New York, Arizona State, and other independent "Virtual Universities" where students can apply for admission, register for courses, purchase books, and attend classes without ever visiting a physical place on campus, have launched similar or more extensive programs (Palloff & Pratt, 1999).

Corresponding to the statement by McIsaac & Gunawardena (1996) that distance learning is the fastest growing form of education, there will be a continued expansion of web-based technologies in higher education. As the web will be increasingly used as a teaching and learning medium, it is important to consider the emerging roles of instructors and its learning environment (Shotsberger, 1997).

Emerging Roles for Instructors and Learners in the Web-based Instruction

A number of authors perceived that the instructor's role in a Web-based setting requires a different set of skills than those employed in a traditional face-to-face classroom. According to McIsaac (1995), the role of the teacher of tomorrow will not be an actor of transmission of just consumption, but will become a facilitator of learning and research as a whole process. Duchastel & Turcotte (1996) argued that we may well see a tremendous growth in informal and out-of-class learning, and the impact of this growth will shift the power in the classroom where the instructor is no longer necessarily the expert. The role of the teacher will shift toward a greater emphasis on guidance and mentoring *(*Thiele, Allen, & Stucky, 1999; Duchastel & Turcotte, 1996*)*. The instructor no longer dispenses knowledge but, rather, guides the student's pursuit of knowledge and provides technical support as educational facilitator (Palloff & Pratt, 1999; Shotsberger, 1997). Rohfeld & Hiemstra (1995) also indicated that the most important role of the online instructor is to model effective teaching and accept "the responsibility of keeping discussions on track, contributing special knowledge and insights, weaving together various discussion threads and course components, and maintaining group harmony" (p. 91).

Those characteristics of instructor roles also corresponding to Berge & Collins' (1996) assertion that categorized the various tasks and roles demanded of the online instructor into four general areas: pedagogical, social, managerial, and technical. They described the pedagogical function as one that revolves around educational facilitation. The social function is the promotion of the friendly social

BEST COPY AVAILABLE

environment, which is essential to Web-based learning. The managerial function involves norms in course setting, pacing, objective setting, and decision making. The technical function depends on the instructor first becoming comfortable and proficient with the technology being used and being able to transfer that level of comfort to the learners.

Shotsberger (1997) mentioned that formalizing and tailoring the interactive environment in the Web-based instruction is considered one of the instructional roles. From a constructivist view, interaction is an important means by which learners construct meaning. Students with higher levels of interaction have more positive attitudes and higher levels of achievement (Thiele, Allen, & Stucky, 1999). By developing Web-based instruction, faculty can create an interactive learning environment that changes the old paradigm of instruction from one of "shoveling knowledge" at the students to one of guiding students through collaborative learning experiences (French, Hale, Johnson, & Farr, 1999; Denning, 1999).

Synchronous and Asynchronous Learning Environments

Eastmond (1995) proclaimed that learners should be given the opportunity to interact, to reflect, and to apply their individual experience in the learning. Also, interactive learning is taking place when the instructor merges both synchronous and asynchronous interactive teaching and learning methods in the Web-based instruction. Berge & Collins (1996) also pointed out that both synchronous and asynchronous interaction teaching and learning methods can be structured as one-to-one (email), one-to-many (listserver managed group), and many-to-many (bulletin boards and dedicated computer conferencing systems).

Relan & Gillani (1997) articulated that WBI offers a new sensibility and means of social interaction employed toward learning. With WBI, cooperative learning extends beyond one classroom to potentially every classroom. Synchronous communication that allows for live interaction (Berge & Collins, 1996) takes the form of interactive messaging systems like computer conferencing tools and chatrooms (Khan, 1997). All participants must be present online at the same time in order to interact. When many people do so, the text on the screen can scroll along at a furious pace with the discussion having much of the flexibility of the spoken word. Harasim, Hiltz, Teles, & Turoff (1995) stressed "The synchronicity of online interactions allows participants time to reflect on a topic before commenting or carrying out online tasks" (p. 27).

Asynchronous communication allows for time-independent interaction that ranges from simple email discussions between individuals that require only the participants have access to an electronic mailbox to feature-rich groupware programs like listserves or bulletin boards (Berge & Collins, 1996). Participants do not have to be online at the same time in order to interact and can do so from any location in which they have access to a networked computer with the appropriate client program.

Theoretically, Web-based learning is available at any hour in which the participant has the ability to access a networked computer. Participants who have access from work, home, or another convenient location may find courses taught by computer conferencing easier to accommodate around work and family responsibilities (Berge & Collins, 1996). Relan & Gillani (1997) also claimed, "the ability of the instructor and students to communicate privately or collectively in a synchronous or asynchronous manner lends a new dimension to the design of instructional strategies" (p. 45). In spite of providing interactive synchronous or asynchronous methods in the Web-based learning environment, Westrom & Pankratz (1997) further stated "the purpose of email, discussion groups, and web pages is to enable communication. These technologies, when combined with procedures designed to facilitate cooperative learning, can lead to the building of learning communities" (p. 2).

Creating a Learning Community

Palloff & Pratt (1999) described the importance of community in the electronic classroom: "In distance education, attention needs to be paid to the developing sense of community within the group of participants in order for the learning process to be successful. The learning community is the vehicle through which learning occurs online" (p. 29). They further concluded that in order to create a successful online learning experience, "the instructor in an online class is responsible for facilitating and making room for the personal and social aspects of an online community" (p. 76). Berge and Collins (1996) referred to this function as "promoting human relationships, affirming and recognizing student's input; providing opportunities for students to develop a sense of group cohesiveness, maintaining the group as a unit, and in other ways helping members to work together in a mutual cause" (p. 7).

Palloff & Pratt (1999) revealed that if a participant logs on to a course site and there has been no activity on it for several days, he or she might become discouraged or feel a sense of abandonment. The situation is related to Berge & Collins' (1996) assertion that

The advantage of computer conferencing includes interaction at a distance with other students and

> the instructor, rather than studying alone. A virtual community can be built that provides support and encouragement and promote sharing among the participants and can help overcome the isolations of remote areas. (p. 4)

A major finding of Gunawardena's (1995) research pointed out the crucial role of the instructional facilitators of computer conferences in creating a sense of community and collaboration among users. Hiltz (1994) also stated three basic principles concerning the instructor's role in distance instruction for establishing and maintaining a learning community: be responsive, be competent online, and organize the interaction. Hill & Raven (2000) recently conducted empirical research examining the best techniques/strategies to enhance learning and community building in WBI. Their results outlined four main categories: atmosphere, foundation, communication, and technology. The technique of atmosphere is to provide a safe on-line environment that learners perceive to be a space where open communication can occur. The foundation strategy is to create structural dependence and organization to assist learners in overcoming information overload, establish patterns, and set expectations to anticipate certain types of communication. Communication strategy is to encourage learners to keep in touch with others and apply technology techniques to provide flexibility in terms of facilitating multiple learning and interactions and minimize glitches.

Web-based learning is sometimes referred to as asynchronous interactivity or asynchronous learning network (Mayadas, 1997), and is defined as people network, anytime, anywhere learning. Romiszowski (1997) concluded the real meaning and importance of WWW networks consisting of computer networks, conversational networks, information networks, and conceptual networks.

Conclusion

Currently, WBI is growing faster than any other instructional technology. The potential collaborative and interactive benefits of WBI have recently caught the attention of institutions of higher education in a profound way. However, WBI is only a delivery mechanism for designing a learning context to individuals. The various aspects of quality, accountability, productivity, and access of WBI had been discussed constantly. Some authors were concerned that critical issues need to be examined before WBI is adopted into university practices, yet many pedagogical factors and theoretical guidelines involved in WBI require to be investigated fully for the success of WBI (Harasim et al., 1995; Berge, 1999).

Breaking the unbreakable: addressing the need for cryptanalysis

William J. Hunter

Network security research

Some time ago, the world of Internet security was brought to life by the seminal work of Clifford Stohl, The Cuckoo's Egg. More recently, books have begun to appear that provide good general introductions to cryptography (e.g., The Code Book by Simon Singh) and to network security more generally (e.g., Secrets and Lies: Digital Security in a Networked World by Bruce Schnier. When Stohl told his story of uncovering a major espionage ring that was using university computers as conduits for the invasion of military computers, one of the most remarkable features of the tale was the complete absence of knowledgeable authorities within the police community, including military intelligence and the FBI. Another critical part of the story was the cavalier attitude of many university-based system administrators who might not even know that the computers they installed came with built-in accounts that had standardized usernames and passwords (which was well known in hacker communities).

Much has changed in the dozen years since Stohl's book was published. Singh's account of the history of "the evolution of secrecy from Mary, Queen of Scots to quantum cryptography" draws on resources from the Second World War that are only now becoming public knowledge. Schnier puts cryptography into a broader social context of network security that indicates both that we have come a long way since Stohl's adventures and that we are still a very long way from anything like adequate security in most computing environments. The questions are of sufficient general interest that a major novel, Cryptonimicon by Neil Stephenson, has drawn heavily on both public key cryptography and a fictionalized account centering on the cracking of Enigma in the Second World War. Finally, the fact that international baccalaureate student Aaron Suggs based his theory of knowledge essay (http://www.ktheory.com/write/extendedessay.htm) on this very topic is one concrete example of the potential for student interest in cryptography as an area of inquiry.

Objectives for a new line of inquiry

The current argument that public key cryptography has given us the capacity to develop unbreakable codes rests on estimates of the amount of computing power/time required to decode an encrypted message. The reasoning seems sound, but the assertion that unbreakable codes exist has been made repeatedly throughout history but eventually those codes succumbed to the efforts of analysts. Nevertheless, there is good reason to take the current claims seriously. If we do so and if we believe that a balance between code-breaking and code-making is important to the success of democratic systems of government (e.g., the ability to defeat Nazism or the potential to uncover terrorist plots), then it becomes important to consider what will be necessary to restore that balance. Among other things, we need to begin work that will

- develop network security as a new area of inquiry in educational technology,
- evoke discussion on critical issues regarding education for and about network security not only for education but for social and political policy,
- provide a basis for informed decision making regarding education for and about network security, and
- establish a body of work that would inform course development in this area.

Proposed directions

The lessons of Turing's Bletchley Park project suggest that many diverse talents can be put to use in the development of a cryptanalytic team. Likewise, it seems likely that cryptanalysis and cryptography could serve as useful integrative themes for an interdisciplinary teaching unit that might be used, with different levels of complexity, at several grade levels. There is already an existing body of children's fiction that is based on code-making and code-breaking concepts that dates back to Edgar Allan Poe's short story, The Gold Bug. Working from this literary base, it is clear that social studies questions around the nature of community, conflict, cooperation and crime could be developed. Further, the connections to history (Bletchley Park, e.g.,) are clear and intriguing as Aaron Scuggs work reveals. Similarly, the use of numeric and algebraic tools in the process of making and breaking codes would provide links to concepts in math curricula and the automating of algorithms for code-breaking is a natural introduction to computer science. Connections to DNA research could relate the study to both biology and chemistry. The final version of this paper will include a delineation of a potential curriculum plan.

Part of the rationale for developing such a curriculum is that it might serve to introduce more students to genuinely interesting and socially useful applications of mathematics. If we are to make a dent in the invulnerability of quantum cryptography, we will need to have substantially more bright minds considering the possibilities of new algorithms that would demand significantly fewer calculations, thus rendering it possible for computers to crack codes in a fraction of the times now projected. This is a long term project that, if successful, might see a payoff many decades into the future. It is thus even more important that the curriculum would raise awareness of the social issues involved in having totally secret communications systems.

Raising the level of concern and debate about such questions will be a prerequisite to developing the kind of problem solving culture the code-breaking will require, but it also would focus attention on the need to avoid succumbing to a sense of futility regarding the potential for evil-doers to benefit from unlimited secrecy. That is, a secure code is only a small part of a secure communications system. Governments will need to be aware of other possibilities for preventing or interrupting conspiratorial communications. A brief discussion of some such possibilities and their educational and policy implications will be a part of the final paper.

Much of this presentation has assumed that the readers have the benefit of good and benevolent government, but civil libertarians could be equally concerned about the potential for government secrecy (or government invasions of privacy) to be as problematic as the potential for crime or terrorism. This is an equally compelling reason for importance of restoring equilibrium (or at least tension) between our capabilities for cryptography and our capacities for cryptanalysis. It would seem, then, that objectives and directions proposed here would have near universal appeal; however, it is quite likely that this will not be the case at all. Strong cryptography has developed in recent years largely to meet the demands of commercial interests wishing to conduct business securely on the Internet. People involved in Internet commerce, both producers and consumers, are likely to see any weakening of the security of Internet transactions as a threat to commerce. While this may be true, I will argue that this threat is more perception than reality, that equilibrium serves commercial interests as well, and that, in the final analysis, commercial losses are a fair price to pay for the security of the social order.

Abstract

We consider that there are two basic problems to solve when a face-to-face teacher decides to incorporate his course to an online system:

- the content's development and
- the role the teacher must assume because of the delivering technology.

Each of these have issues to be considered. While the content's development stage requires an interdisciplinary team to assist the teacher graphically, didacticly and ergonomically, the facilitator who instructs an online course deals with the student's new role and his personal circumstances as well as the new learning environment.

During this presentation we will talk about the main problems and solutions we faced to develop, deliver and instruct on-line courses.

Introduction

Distance education systems represent a huge opportunity for those people who, for whatever reason, cannot attend a classroom (geographic, health, work schedule limitations).

In this educational system, the computer and specifically the Internet, are becoming very popular. Secondary educational courses, masters degree programs, certificates, etc., are all offered as web-based courses.

The Academic Computer Center is, among other things, responsible for bringing computers and telecommunications training to the Mexican population. In order to reach more people from different states, as well as those who are unable to attend a classroom, training at a distance has become an important goal for the institution.

The Interactive Products department is focused on developing online learning materials as well as research and helping teachers adapt the curricula and its contents for the web.

Even though web-based courses are constantly increasing, we are just beginning to establish development standards as well as new didactic strategies focused on this media. We are aware that a lot of people are working on this objective and that is why we are considering the sharing of our experiences and ideas.

Content

The Interactive Products department was founded in 1997 with the goal to develop supportive online learning and teaching materials, for the face-to-face courses given at the Computer Centre.

The main reasons for this decision were:

- free teachers from spending too much time developing supportive materials
- facilitating teachers and students supportive materials accessible at all times
- research on educational applications using the new technologies

In two years, on-line tutorials, educational games, quizes and simulators were developed by the department.

The success obtained by the use of these enhanced the research and development of other educational materials. Teachers and researchers came to us for assistance and training to generate on-line materials. As time passed, we saw that training and teaching at a distance was a trend for the university, and becoming stronger each day.

Our first on-line course was a pilot project and was given internally in our department. Conceptual maps was the subject to be taught, in order to know a little bit more about the teaching strategy that teachers were talking about.

The first step was to collect data (from articles, books and on-line materials). Then we decided the curricula to be covered during the three weeks course (aproximately, 30 hours). The next important step was to write the introductory notes for each unit; they were brief notes along with articles, on-line resources and activities to enhanced independent study. At this point, we began to build the interface and to programm the interactive applications that were needed. A graphic designer, an interface designer and a programmer were responsible for these activities.

The website's architecture was simple and easy to use. There were basically two screens. The main screen had general information about the course, and the second screen (after logged in) had several options: instructions, agenda, group information, discussion forum, mail service to the teacher, blibliography, activities and units.

The course started with 20 people, most of them had never taken an on-line course before neither did we had taught at a distance either. The main problems the tutor had to deal with, were:

- Because the course was an obligatory one for all members of the team, some of them were not really interested on the subject.
- Even though all people in the department work with computers and Internet, they were not familiar interacting as a group through the web.
- Most of the persons were not used to studying independently.
- It was difficult to motivate students to interact through the forum and to follow discussions.
- Most people didn't pay attention to the agenda or the deadlines.

Taking into consideration these experiences, we built two more internal courses: UNIX and JavaScript. This time they were not obligatory and only those people interested in the subjects were registered.

We added another option for those students that wanted to review the units already seen and designed more activities to be done through the forum.

In order to offer the first three courses to the public, we had to answer some questions about online instruction.

- How do we administer our time in order to help all students?
- How many e-mails do we respond to daily?
- Which is the optimum way of moderating an online discussion?
- How do we promote students' interaction in the forum?
- How often do we need to participate or ask new questions to be discussed?
- When do we use the e-mail and when do we use the forum?
- How can we make students meet their deadlines?

Even though every online course is different and every teacher and student has their own teaching and learning style, we felt, based on our experiences, that there were some important issues to be considered and that will help answer the questions above:

Independent Study. The online courses we have developed are based on independent study. We encouraged students to read, analyze, investigate, experiment and discuss, in order to construct knowledge. That is why it is important to let the student face the problems, to be a facilitator instead of a tutor; he should provide guidance and not solve problems.

Follow-up. When a student sends an e-mail to the facilitator, it is very useful that he receives a "received message" from the facilitator. Another issue that needs to be tracked is "activity". It is common that at the beginning of the course, students start very enthusiastically, but as the course progresses, they participate less. It is then that the facilitator should encourage them to be active and not passive; by asking them if there are any problems or by proposing a discussion or an activity.

Discussion Forum. This space is designed for students to interact as a group; they will be able to exchange messages, experiences and doubts. It will help student feel part of the group along the course. The tutor follows the discussions and participates when he thinks it is necessary (solving a general doubt, bringing up new questions and maintaining the discussion).

E-mail. Students that need or want to interact exclusively with the tutor are encouraged to use e-mail, either to solve a specific question, to comment on any task or to send assignments. It is very important to specify, at the beginning of the course, the amount of time and specific hours that the tutor will be available, in order to have time to do other activities acide from tutoring.

Evaluation. In order to verify a student's progress and his achievement, several problems to be solved are presented; the level of complexity of each of them increases as the course advances and, at the end, they must develop a project that integrates the most important concepts reviewed and that are related to his daily activities.

Results

The results obtained were satisfactory, so we decided to establish this architecture as a model for the next online courses . At this moment we have seven online courses and four online tutors. It is important to mention that a face-to-face teacher tried to teach at a distance but did not develop the skills needed to interact with students and did not feel comfortable with online teaching. Also we found several teachers that did not finish developing the courses' contents because, either, lacked the time or lacked motivation and commitment.

The following table shows the average results obtained on six courses:

Registered students	111
Students that finished the course	83
Students that obtained the certificate	80
Students that registered on another course, after the first experience	11

Conclusions

- It is convenient to have an interdisciplinary team to develop online courses.
- It is important that institutions support teachers developing online content, giving them time and, in some cases, money for their work.
- An optimal learning environment involves not only instructional materials, but also the interface design, its usability and interactivity.
- Optimal learning environments enhance students to enroll again to an online course.
- Online facilitators must be trained.
- Feedback and interactivity are key elements to success in an online course.
- Even though students need to change their learning skills, they are ready to make the effort to adapt and incorporate to online courses.

Abstract In order to discover a potential relationship between instructional interventions and the judgments, confidence, and perceived cognitive load of preservice teachers, we performed a study to examine different instructional methods aimed at facilitating preservice teachers' judgments about the credibility and cognitive load aspects of Web-based resources. Participants were ask to rate whether the web sites were considered objective and accurate, mistaken, or purposely misleading and give reasons for their decision both prior to and after different instructional methods. We found that the confidence ratings varied considerably but the judgments themselves did not. This gives educators hope that evaluation skills may be taught that are general enough that students can apply them to a variety of web sites.

Introduction

As the use of resources from the World Wide Web become more prevalent in today's classrooms at all levels, the need for critical evaluation skills is increasingly important. In our research, we have examined differences between scientists' and preservice teachers' ratings of the credibility of different information sources for learning scientific information and found some interesting differences (Klemm, Iding, & Speitel, 2001). We have also carried out instruction in Web evaluation with high school biology students (Iding, Landsman, & Nguyen, in press) and university-level preservice teachers (Iding & Klemm, 2002), and we have examined differences between preservice teachers and computer science students in their judgments of credibility of Web-based resources (Iding, Auernheimer, Crosby, & Klemm, 2002). In the present paper, we briefly describe findings from this line of research and propose a new study that will examine an instructional intervention aimed at facilitating preservice teachers' judgments about the credibility and cognitive load aspects of Web-based resources.

Research Review

In previous research we compared preservice teachers and scientists' ratings of the credibility of a number of different kinds of information sources for scientific information, including weekly newsmagazines, information from the Internet and resources from museums (Klemm, Iding, & Speitel, 2001). We found interesting differences between scientists' and preservice teachers' ratings. For example, scientists attributed a higher level of credibility to a scientist researching a topic. In contrast, preservice teachers attributed higher credibility ratings to information sources like TV newsmagazines, while scientists rated them less highly. In our conclusion, we argued for the need for instructional interventions.

In subsequent research, we carried out several sessions of instruction with high school biology students about evaluating the credibility of Websites and the science information contained in them (Iding, Landsman, & Nguyen, in press). After instruction students reported that they would spend more time assessing the credibility of websites in the future, provided lists of criteria for assessing websites that were more comprehensive than when they were pretested, and reported increased confidence about their critical evaluation skills with respect to web-based science information.

In other research, we worked with university-level educational psychology and computer science students. We asked them to rate the accuracy and objectivity of information on websites (related to class topics) and their confidence in their abilities to effectively evaluate course-relevant information effectively on the World Wide Web and generally (Iding, Auernheimer, Crosby, & Klemm, 2002). We found that educational psychology students rated their ability to assess the validity of information in their field more highly than computer science students, but educational psychology students rated their ability to assess the validity of information on the Web less highly than computer science students. Notions of website authors' vested interests seemed particularly problematic for some students. We called for the importance of further instruction and research in this area (Iding, Crosby, Auernheimer, & Klemm, 2002).

In another instructional study, we worked with preservice teachers in educational psychology classes to determine what criteria they use when evaluating science websites for credibility and cognitive load (Iding & Klemm, 2002). To provide some background, the concept of cognitive load is particularly relevant to learning effectively with multimedia and media-rich environments, such as those presented on Websites. Chandler and Sweller's (1991) and Sweller and Chandler's (1994) work provides the foundation for much of the current work in this area. Specifically, they argued that cognitive load can be increased and negatively impacted when instructional formats create needless redundancies (i.e., "redundancy effects") or foster integration from multiple, separate information sources (i.e., "split attention effects"). Other factors can contribute to detrimental increases in cognitive load as well, including distracting multimedia effects.

Instructional Intervention

We believe that in addition to making effective judgments about the credibility or validity of information, it is also important for future teachers to be selective and informed about the most effective types of multimedia for students, as it cannot be assumed that because a website or other information sources. Therefore, in this study, in addition to studying we gave preservice teachers a brief introduction to aspects of cognitive load related to instructional formats.

First, we asked students to provide preliminary lists of criteria that they use when determining whether to use information from a website. We provided students with a brief introduction to the concept of cognitive load and to website evaluation criteria that we derived form the work of Farah (1995) and Rader (1998) and adapted in the work of Nguyen (2000) and Iding, Landsman and Nguyen (in press). Then, students worked in pairs to evaluate and rate actual websites for credibility and cognitive load, and in small groups, they engaged in a brainstorming activity around effective credibility criteria. Lastly, we asked them to create rubrics for students assessing the credibility of Website information, and for teachers determining the cognitive loads associated with Websites. Our findings indicated that students had some useful and interesting ideas for rubrics, however our instructional intervention was short and the rubrics created by some students for assessing cognitive load included credibility criteria as well.

In the present research, we describe interventions with preservice teachers. In these intervention methods, we provide specific instruction over several sessions for activities related to helping them develop effective strategies for assessing credibility and cognitive load/multimedia aspects of Websites. In addition to fostering effective credibility judgments (and effective ways to teach this important aspect of technological and scientific literacy to their students), our goal is to also investigate effective ways for them to assess cognitive load associated with websites and multimedia presentations that they might select for their students.

Acknowledgements

Trust and the Internet: Findings from the HomeNetToo Project.

Linda A. Jackson, Gretchen Barbatsis, Alexander von Eye, Frank Biocca,
Yong Zhao and Hiram E. Fitzgerald
Michigan State University

HomeNetToo is a longitudinal research project funded by the National Science Foundation to examine the antecedents and consequences of home Internet use in low-income families in the United States.[1] Participants in the project are African American and European American families who agreed to have their Internet use continuously recorded, complete surveys at multiple points during the 18-month project, and participate in home visits during which instruction on how to use the Internet was provided. In exchange, participants received home computers, Internet access, and in-home technical support. Among the antecedents of Internet use considered in the project were trust-related beliefs about the Internet. In this report we focus on relationships between trust-related beliefs, demographic characteristics and Internet use. Structural equations modeling is used to describe these relationships.

Trust has long been recognized as a core personal characteristic that influences a broad range of behaviors (Erikson, 1963). Yet despite recognition that trust is a "quintessentially human trait," much of the research on trust in a networked society has focused more on the technology than on the people who use it. Technological fixes to concerns about trust have filled research agendas. But as May argued (2000), this emphasis on "things" rather than on people will never resolve the central issues surrounding trust in a digital world. Similarly, Rosenbloom (2000) closed the introduction to the Communications of the Association of Computing Machinery special issue on trusting technology with this comment: "answers to questions about technology-mediated trust might ultimately depend on changing human attitudes and behavior - a challenge certainly greater than any of those involving technology alone."

Research and public opinion polls support the view that trust is a critical issue in the future of Internet, and in the use of technology in general. A Gallup poll (February, 2000) reported that half of U.S. Internet users have serious concerns about the trustworthiness of the Internet, particularly about privacy and security of information. A later report by the Pew Internet & American Life Project (August, 2000) found that both users and nonusers of the Internet have serious concerns about privacy. Similarly, the UCLA Internet Reports (2000, 2001) revealed deep concerns about privacy, the ease with which children can access inappropriate content, and the trustworthiness of information on the Internet. In the HomeNetToo project we examined trust-related beliefs about the Internet and how beliefs related to actual Internet use.

Methods

Participants and Procedures

Participants in the HomeNetToo project were 117 adult residents of a low-income, mediumsize urban community in the mid-western United States. Participants were primarily African American (67%), female (80%), never married (42%), and earning less than $15,000 annually (49%). The majority reported having some college education (49%) or earning a college degree (13%). Average age of participants was 38.6 years old. Surveys completed at pre-trial, three months, and nine months included measures of trust-related beliefs about the Internet and demographic characteristics. Internet use was automatically server-logged throughout the project period.

Measures

Four measures of Internet use are considered in this report: time online (minutes/day), number of Internet session (log-ins/day), number of unique Web domains visited (per day), and number of e-mails sent (per day). Internet use measures were divided into two time intervals: Time 1: months 1-6; Time 2: months 7-12.

The five trust-related beliefs about the Internet were as follows: There is no privacy on the Internet; Most of the information on the Internet is true; No one can find out what you're doing on the Internet; Children can come to harm if they use the Internet; Using the Internet can cause health problems. Five-point rating scales were used; higher values indicated stronger agreement with the belief statement. Because there was no change in trust-related beliefs between pre-trial and later assessments (i.e., three months and nine months), only pre-trial measures are considered in this report.

Also measured at pre-trial were demographic characteristics (i.e., gender, race, age, income, education) and previous experience using the Internet, assessed by four questions (e.g., How would you rate the extent of your experience with the Internet? 1=no experience, 5=a great deal of experience).

Results and Discussion

Relationships between trust-related beliefs and Internet use are presented in Table 1. During the first six months of home Internet access, believing that most of the information on the Internet is true was *negatively* related to all measures of Internet use. Believing that no one can find out what you're doing on the Internet was *negatively* related to number of Internet sessions and number of e-mails sent. Believing that using the Internet can cause health problems was negatively related to number of domains visited and number of e-mails sent.

Table 1: Relationships between trust-related beliefs and Internet use

	Time online (minutes)	Number of sessions	Number of domains visited	Number of e-mails sent
Time 1 (1-6 months)				
There is no privacy on the Internet.	.11	.15	.17	-.05
Children can come to harm if they use the Internet.	-.01	-.04	-.08	-.19
Most of the information on the Internet is true.	-.19*	-.28*	-.24*	-.30*
Using the Internet can cause health problems.	-.13	-.15	-.22*	-.36*
No one can find out what you're doing on the Internet.	-.09	-.20*	-.11	-.26*
Time 2 (7-12 months)				
There is no privacy on the Internet.	.20*	.20*	.22*	.20*
Children can come to harm if they use the Internet.	-.07	-.15	-.07	-.17
Most of the information on the Internet is true.	-.29*	-.29*	-.31*	-.55*
Using the Internet can cause health problems.	-.14	-.23*	-.20*	-.23*
No one can find out what you're doing on the Internet.	-.21*	-.24*	-.21*	-.22*

Note. Numbers are correlations (Pearson) between belief measures and log transformations of Internet use measures. *p<.05.

During the next six months, *negative* correlations between believing that most of the information on the Internet is true and using the Internet were stronger than during the first six months. Similarly, believing that no one can find out what you're doing on the Internet was again *negatively* related to Internet use, not only to number of sessions and number of e-mails sent, as during the first time interval, but also to time online and number of domains visited. Believing that there is no privacy on the Internet was related *positively* to all measures of Internet use during time interval 2, relationships that were not significant during time interval 1. Finally, believing that using the Internet can cause health problems was again negatively related to number of domains visited and number of e-mails sent, as in time interval 1, and also to number of Internet sessions.

Race differences in Internet use were obtained at both time intervals. During the first six months, African Americans participated in fewer Internet sessions (M=.70) than did European Americans (M=1.21; F(1,108)=6.83, p<.01). Race differences were more pronounced during the second time interval. African Americans spent less time online (M=38.08), participated in fewer Internet sessions (M=.41), visited marginally fewer domains (M=8.43), and sent fewer e-mails (M=.14) than did European Americans (Ms=45.61, 1.00, 15.61, .99, respectively; F(1, 114)=5.83, p<.05, F(1,114)=8.56, p<.01, F(1,114)=3.10, p<.08, F(1,114)=4.96, p<.05, respectively).

Age differences were only marginally significant during the first six months of home Internet access. Older participants (age 38 and above) engaged in somewhat fewer Internet sessions (M=.68), and visited fewer domains (M=7.94) than did younger participants (Ms=1.07, 12.27, respectively; F(1,108)=3.65, p<.06, F(1,108)=3.02, p<.09, respectively). Age differences were more pronounced during the second time interval. Older participants spent less time online (M=30.66), participated in fewer Internet sessions (M=.49), and visited fewer domains (M=8.80) than did younger participants (Ms=52.67, .74, 13.07, respectively; Fs(1, 114)=4.65, 4.60, 5.13, ps<.05).

Previous experience using the Internet was only modestly related to Internet use. During the first six months, participants with more experience spent somewhat more time online (r=.18, p<.07), visited more domains (r=.21, p<.05), and sent more e-mails (r=.25, p<.05) than did less experienced participants. During the second six months, more experienced participants spent more time online (r=.20, p<.05) and visited more domains (r=.20, p<.05) than did less experienced participants.

Structural equations modeling was used to explore relationships among trust-related beliefs, previous experience, demographic characteristics and Internet use (LISREL, 8.2, Joreskog & Sorbom, 1991). The model presented in Figure 1 is the result of exploratory rather than confirmatory analysis of a theory-based model. Nevertheless it provides a moderately good fit to the data ($\underline{P}^2(81)=166.81$, $\underline{p}<.01$, RMSEA=.096, AGFI=.76, NNFI=.85). Moreover, tests of alternative models indicated that none was statistically or conceptually a better fitting model (i.e., changes in PNFI < .06).

In the model the effects of race and age on Internet use are mediated by their effects on trust-related beliefs about the Internet, specifically, beliefs about privacy, confidentiality, and reliability of information. African American and older participants were more trusting of the technology than were European American and younger participants (respectively), and this trust was related to less Internet use at both time intervals. There was also a tendency for participants who believed that using the Internet may have negative consequences for children and health to use it less, but these effects were not statistically significant. Thus, participants who distrusted the technology but did not believe that using it would harm children or health used it more than did participants who trusted the technology but were concerned about its impact on children and health.

mSupport -- supporting the mobile student

Di James and Nathan Bailey
Flexible Learning and Teaching Program
Monash University

Abstract

Portals provide a valuable mechanism for providing a unified, personalised environment for accessing information -- a one stop shop for students to manage their relationship with the University. Increasingly, however, institutions are looking for ways to disseminate key information to students, while taking care to avoid information overload. This paper explores the way that technologies such as SMS (mobile phone text messaging) and workflow can allow students to direct crucial information, including academic information, in the way that is most convenient for *them* to receive them.

Introduction

Portals are a proven technology and are increasingly used in higher education for learning and teaching, research, staff and student support and administration. They will almost certainly be a part of any Information Technology architecture that is established in the higher education sector, to manage the appropriate, relevant and secure collection, storage, publishing and access and dissemination of information (Information Management). Other technologies that can contribute to the dissemination of information and provide efficient cost and time alternatives to email are emerging as adjuncts to institutional portals. The use of text messages sent to mobile phones (SMS) is an example.

Monash University now uses SMS to distribute examination results at the end of each semester, in conjunction with the online release of results accessed via the university portal. We propose to investigate the use of SMS for additional academic, administrative and social functions. We are however concerned that issues related to Information Management, including privacy and security need to be addressed.

mContact -- taking advantage of a highly 'mobile' demographic

The ownership of mobile phones in Australia is now 69% and there is a higher % ownership among young (15-24) and middle (25-49) age individuals.
(http://www.tnsofres.com/apmcommerce/product.cfm)

The use of text messages by young mobile phone users in Australia prompted an interest several years ago in testing the viability of this medium for communication with students. Consequently, Monash University piloted what was quite possibly a world-first in distributing unit results directly to student's mobile phones. SMS has now been successfully implemented as a cost effective and highly appealing distribution channel for student administrative information. This service continues to be one of the most popular services we offer to students, with continuing positive feedback every semester. Now institutions are starting to look at how to use this valuable avenue for disseminating other kinds of information.

We speculate that the very strong acceptance of text messaging by students could indicate that it has a role to play in other areas, as well as supporting additional administrative functions. General email to class lists requires login to a computer and is often ignored, but SMS is immediate and personal and has the potential to be a more attractive medium for communication with students. Uses might include communication of assignment information, topics, venues and social activities, by teaching staff within individual subjects or courses. It could also be used to comment on topics, readings or current events that come to hand during semester. Pilot programs are now being established to test the potential within higher education of SMS in conjunction with institutional portals to extend functionality and increase effective communication

Some of the issues that arise are related to security and privacy and to the emerging concern with information management systems within higher education generally.

Information dissemination

Much of our support for students is in response to their needs, rather than actually being proactive and taking the information they need to them. Messaging and workflow technologies provide the opportunity for students to profile the information they want, in they way they want it, thereby allowing the University to be much more proactive in information dissemination.

Some courses are beginning to establish announcement forums, either in email or discussion groups. However, such forums can be regarded by students as generic announcement emails, and students ignore them. It would appear that there is no sense of the gravity of the issues or the areas of interest to the recipients.

Technology offers two promising solutions toward this need – choice of content, and choice of forum. Some information is essential for participation in a unit of study (e.g. the time/location of the mid-semester test has changed), other information is merely helpful for those students who choose to pursue it (e.g. "there is another reading on this topic at this URL"). However, it is not always clear what information students regard as urgently important and what information they would prefer to browse at their leisure. Students need to be empowered not only to choose what information they receive, but how they receive it. Instead of them feeling overwhelmed with information that is only of passing interest to them, they should be able to process specific items exactly as they wish to.

This could be achieved using SMS messages (i.e. text messages to mobile phones) and Workflow (i.e. the workflow component on my.monash). In terms of workflow, many of the processes we complete both in our jobs and in learning and teaching can be set up as a series of steps that allow each person involved in the process to pick it up from their in tray, do their bit, and pass it on to the next person's in tray. Sometimes we do this by email, sometimes we do it by phone, but (sadly) often we do it by paper forms that are subsequently entered in to a computer!

Electronically supported workflow ensures that the information is stored electronically, the status of the task is identifiable to everyone involved in the process and the task is automatically distributed to the next person or group of people who need to participate in the process. In increasing transparency to the entire process, students can be sure that their form/request wasn't just "lost in the mail" but has actually been actioned with an identified outcome.

Such workflow could be useful for requesting/granting extensions, proposing/responding to social events (e.g. RSVP for course/department BBQ.

Advantages

Monash has 45,000 students enrolled over 8 campuses – 6 metropolitan or regional Australian campuses and 2 offshore (in Malaysia and South Africa) and frequently studying off campus. Mobile information dissemination is equally as important as mobile academic content delivery. The university portal, online content and use of SMS for administrative services provides for much of the successful management of information services including academic services. An exploration of the use of SMS to provide additional support for academic delivery and student/teacher communication is now seen as potentially beneficial for both enhancing communication and for cost effectiveness.

The cost of publishing to the web and bulk SMS services to nominated phone numbers is highly competitive, compared with the cost of producing and posting hard copy to students, particularly when many are off campus.

Issues

Some of the issues that arise are related to:

- the obvious requirement that technology supports, not drives, learning - core academic activity must be facilitated, not undermined, by technological developments – but innovation must be supported to determine the potential of new technologies.
- security - SMS messages are sent to a mobile phone number nominated by the student. There is some concern that unauthorised persons could have access to the phone and therefore to confidential information (eg exam results). This issue has been managed by ensuring that students read the

security and privacy information when they nominate to receive confidential information via SMS and sign off on a disclaimer.

- privacy – The matter of keeping records of transactions with students, their access to records and the somewhat 'ephemeral' nature of SMS is somewhat more difficult to manage. In this context, it *relates to more* general issues of information management that are currently of concern to higher education institutions - data storage, collection and dissemination, publishing and access to information etc.
- equity – Use of particular technologies that rely on student ownership of equipment must be considered in the context of any disadvantage caused by students choosing not to use, or being financially or physically unable to use the equipment
- the emerging concern with information management systems within higher education generally.

Conclusion

The use of SMS to mobile phones provides a cost advantage for the delivery of administrative information to students. While this is an obvious benefit to both students and the university and will continue to be used, the use of SMS and other emerging communications technologies for academic purposes needs to be considered carefully and creatively. The place of these technologies in the emerging Information Management systems architecture will also need to be considered along with appropriate policy development.

E-Learning Strategic Planning Utilising a Work Systems Framework

Abstract: This paper examines the various work system elements that should be considered by school administrators when developing e-Learning strategies in traditional teaching and learning contexts. Focus group interviews were conducted with teachers in a secondary school in Sydney, Australia in order to identify the work system elements involved when using the Web for student-centred learning activities. The findings of the analysis are provided and the associated implications for the development of school e-Learning strategies are also discussed.

Introduction

The 'information revolution' has forced most OECD economies into an era which demands 'knowledge workers' for the 'knowledge economy' (OECD 1996). As a result, schools are placed in a situation requiring reassessment of their methods of practice, adapting and improving teaching and learning for the changing needs of a global, digital, and networked economy. While global spending on e-Learning in educational institutions is increasing at unprecedented rates (OECD 1998), the pressing problem for school administrators is that the rate of adoption by teachers across all sectors of education has lagged significantly behind that of industry (Leidner & Jarvenpaa 1995). Latham (1998) suggests that any organisation wishing to make changes to their processes by incorporating information technology (IT) into their activities will require a strategy as an essential part of the management of change. She describes *strategy* in terms of creating a vision of the future and formulating the means and policies that will enable the organisation to reach that vision. Latham points out the potential for schools to effect strategic use of IT in such areas as curriculum delivery and the provision of students and teachers with access to knowledge bases. She argues that in order to achieve these strategic objectives, schools need to identify and develop an information systems strategic plan that should be based on business needs, and derived from an analysis of the business, its environment and business strategies. While most of the literature on information systems (IS) strategy relates to the business goals of making profits and surviving in a competitive environment, schools also have organisational goals and need to manage resources effectively in order to meet those goals. In order to develop IS/IT strategies, school administrators would benefit from adopting a framework for analysing the underlying work systems involved in various aspects of e-Learning.

Work Systems and E-Learning Strategy

Alter (2002) suggests that the use of the *work system framework* will assist organisations in the process of conducting a thorough systems analysis that will assist in the process of strategic integration of information and communication technology. Alter suggests that one common pitfall made in defining e business models, is that the business process is defined so broadly that it involves a wide range of products and customers and is difficult to analyse coherently. He argues that this pitfall can be overcome through a focus on *work systems* defined as "systems in which human participants and/or machines perform a business process using information, technology, and other resources to produce products and/or services for internal or external customers". Alter defines the eight linked elements that can be used to summarise any work system. *Customers* are the people who use and receive direct benefits from the products and services produced by the work system. *Products* are the combination of physical things, information, and services that the work system produces for its customers. The (business) *process* is the set of work steps or activities that are performed within the work system. *Participants* are the people who perform the work steps in the business process. *Information* is the information used by the participants to perform their work. *Technology* is the hardware, software, and other tools and equipment used by the participants to perform their work. *Context* is the organisational, competitive, technical, and regulatory realm within which the work system operates. *Infrastructure* is the shared human and technical resources that the work system relies on even though these resources exist and are managed outside of it. This typically includes human infrastructure such as support and training staff, information infrastructure such as shared databases, and technical infrastructure such as networks and programming technology.

As part of a larger study on eLearning in Australian schools, a small group of four Australian Mathematics, Science, Social Science, and Humanities secondary school teachers were interviewed to conduct an analysis of the work system involved when using the *Web* for student-centred learning activities. In this paper we provide a summary of this analysis and highlight the critical success factors that should be considered when formulating an e-Learning strategic plan in the context of this particular school.

Findings

Prior to conducting the analysis, we first considered the traditional means by which student-centred learning activities are performed and subsequently identified the *rationale* and *strategic goals* associated with the introduction of the *Web for student-centred learning* (Tab. 1).

Rationale: Instead of students going to traditional sources such as for books and/or journal articles in library, encourage them to access the latest information on-line from home, or during class via school computer network.
Strategic Goal: Develop student skills: use of IT and Web, independent learning, information literacy, 'knowledge work', and problem solving.

Table 1: Rationale and strategic goals of the Web for student-learning

The next step in the work system analysis involved the identification of the general work system elements, the associated critical success factors (Alter 2002), and some broad implications for school management when formulating the IS/IT strategic plan (Tab. 2).

Customer: Students use the Web for independent learning activities (research project). *Products:* Completed research project demonstrating student's ability to synthesise information into knowledge applied to the project. Development of students' independent learning skills and other generic skills. Teacher assessment and feedback on student Web research skills.

Success factors: Product design consistent with customers needs (Alter 2002). *Implications:* In this case, teachers will need to develop projects and student-centred activities commensurate with student information literacy and independent learning skills. The pedagogical implications and objectives of e-Learning will need to be understood by teachers and aligned with student research tasks and appropriate assessment guidelines. Therefore teachers require adequate training, prior research on topic, and alignment with overall curriculum and course objectives.

Process: Teacher sets Web research project. Student uses Web search engines and/or on-line journals from home or via school computer network. Student types in relevant key words and decides which information is relevant. Student analyses and sorts through relevant information and synthesises to produce project (product). Teacher assesses and comments on quality of products (project and student information skills). *Success factors*: Fit of process with other elements of the work system; Adequate resources for process; Effective operational management (Alter 2002). *Implications:* Teachers need skills in developing, managing and assessing these projects. They need to ensure students are adequately trained and have developed effective search strategies. For example, Boolean logic (the expressions *and*, *or*, and *not*) requires higher order skills. Teachers also need to ensure that sufficient time, adequate on-line resources are available, and equitable access is available to students conducting the research. Finally, teachers will need to ensure that IT support staff are aware of the process and are attentive to any system disruptions during the project time frame. Teachers therefore need training and support to ensure effective planning and management of student-Web research activities.
Participants: Students using Web. Teachers setting and marking research projects. IT-support staff. *Success factors*: Appropriate skills and understanding; Interest in doing this type of work; Motivation to do this work in this setting; Ability to work together to resolve conflicts (Alter 2002). *Implications*: Adequate training for both students and teachers will be integral to the success of the system. Well qualified IT support staff are required, along with accessible, functioning networked terminals. Management needs to foster a collegial working environment. Understanding of the learning implications for students is also crucial. If managed effectively, the above factors will also have implications on the motivation of the participants involved in the work system.
Information: Student gathers: information on research question. Key words for search. Hyperlinks to Web pages. Information on research question. Teacher inputs: Information on research project. Feedback to student on work. Assessment grade into school reporting system. *Success factors*: Adequate information quality; Adequate information accessibility; Adequate information presentation; Adequate information security (Alter 2002). *Implications*: Apart from the aspects of training, support and equipment discussed above. Teachers will need to ensure that the browsers, terminals and monitors are adequate for displaying information. Further, that the school network has appropriate security measures in place such as firewalls and up-to- date anti-virus software. Teachers also need to ensure that they have developed adequate methods for presenting students with assigned tasks and feedback.
Technology: Personal computer used by student with modem from home or on school computer network. Computers and networks used by the various search engines. *Success factors*: Ease of using the technology; Adequate technology performance (having enough 'horsepower'); Maintainability (how easy it is to keep the technology operating over time); Compatibility with technology in related systems (Alter 2002). *Implications*: The provision of adequate training, maintenance plan, and support staff. Careful consideration of the above factors when planning and acquiring hardware such as PCs and network components. Also important when selecting software, Web browsers, and subscription to ISP.

Table 2: Work system analysis for Web use in student-centred learning

The final step in our analysis involved analysis of teacher comments regarding the current context and infrastructure within which the work system is situated (Tab. 3). The analysis in Table 3 highlights several key *structural* problems related to the *context* and *infrastructure* within which this work system is currently situated. These issues need to be addressed by the highest level of school management as part of the strategic planning process and present major obstacles to the integration of the Web into student learning activities.

Current Context: The timetable (based on 50-minute periods); curriculum requirements; school culture; teacher IT training and skills; and classroom layout; are all consistent with the traditional teaching and learning environment in this secondary school. Student demographics also suggest that a large proportion of students currently do not have access to the Web from home and therefore equity issues affect teacher utilisation of the Web in this work system. *Strategic Implications for Management:* Top management support and initiative is required in addressing some of the organisational issues presented above. Management needs to work on changing the school culture to become more compatible with the new work system. They need to facilitate and foster cooperative decision-making regarding the adoption of the new work methods. They need to foster a teaching and learning environment that reduces the level of turmoil and distraction between the various contextual components addressed above and the new work system (Alter 2002). For example, one suggestion is the provision of a single dedicated classroom to each key learning area (e.g. Science) with appropriate layout and a high ratio of networked terminals. Combined with restructuring of the timetable to allow for at least one double period per week for each class in each subject. This set of initiatives would allow for decentralised lesson planning by teachers in each key learning area. Teachers in each faculty could coordinate their use of the room when required and organise integrated student Web activities during the double periods. If the single computers, currently under-utilised in each classroom, were placed in the dedicated classroom, it would potentially lead to more effective utilisation of existing resources.
Infrastructure: Web access exists through school computer network. However, the service is slow and while access is possible through dedicated computer labs and the school library, the facilities are often reserved for dedicated IT classes during normal school periods thus rendering it difficult to integrate with lessons in the other key learning areas such as science. At best, one networked computer may be available in the normal classroom and in many cases these are not functioning properly. Also, it is difficult to access IT support staff when problems arise and further the skills of the support staff do not seem to be sufficient to correct the problem in a timely manner. *Strategic Implications for Management:* Need to provide adequate *technical* and *human* infrastructure for the integration of the Web into student learning activities (Alter 2002). For example, at this school, more computers are required in classrooms, more powerful servers and greater bandwidth is required for this school network. A higher ratio of suitably qualified support staff is also necessary. While these issues are costly, the school management has a duty to provide these services in order to achieve the strategic objectives. Leasing arrangements may assist.

Table 3: Current context and infrastructure and strategic implications for management

The analysis in this study highlights the importance of work systems analysis as a framework for strategic planning for the integration of e-Learning in schools. The findings suggest that this framework can be utilised at various phases throughout the systems development process and has several implications including: the design and planning of educational technology courses for teachers; e-Learning resource location and acquisition; and information and communication technology infrastructure planning.

Abstract: This paper reports the findings of a study which utilised diffusion of innovations theory to examine Web adoption by teachers in a secondary school in Sydney, Australia. Data collected through a survey questionnaire was used to examine teacher perceptions regarding various attributes of the Web as a tool for both teaching preparation and delivery. Our analysis of the data suggests that the innovation attributes of relative advantage, compatibility, visibility, ease of use, result demonstrability, and trialability should be considered by school administrators seeking to increase the rate of Web use by teachers in their schools. The image attribute did not emerge as significant in either of the contexts examined. Implications for the development of strategies for e-Learning diffusion are discussed including practical examples.

Introduction and Background

The adoption and effective utilisation of e-Learning is an important issue to educators around the world. In the context of Australian schools, Gibbons (2001) reports that 98% of teachers from K to 12 are using the Internet but only to perform basic tasks such as e-mail and research via search engines mainly for *teaching preparation*. Gibbons suggests that the majority of Australian teachers are still struggling to incorporate Internet applications such as Web publishing with traditional methods of *teaching delivery*. In this study we use *diffusions of innovations* (DOI) theory to examine factors affecting the *adoption* of the Web by teachers in an Australian secondary school.

Rogers (1983) DOI theory defines five attributes or characteristics of innovations which influence an individual's attitude towards an innovation during the adoption process. These attributes include relative advantage, compatibility, complexity, trialability, and observability. *Relative advantage* is the degree to which an innovation is perceived as better than the idea it supersedes. *Compatibility* is the degree to which an innovation is perceived as being consistent with the existing values, needs, and past experiences of potential adopters. *Complexity* is the degree to which an innovation is perceived as difficult to understand

and use. *Trialability* is the degree to which an innovation may be experimented with on a limited basis. *Observability* is the degree to which the results of an innovation are observable to others.

Based on DOI theory, Moore and Benbasat (1991) developed an instrument to measure an individual's perceptions about using an information and communication technology (ICT) innovation. Moore and Benbasat renamed Rogers' complexity construct as *ease of use*, consistent with Davis (1989). They also developed the *image* construct defined as the degree to which use of an innovation is perceived to enhance one's image or status in one's social system. Also, during the process of developing the instrument, they found that the construct of observability separated into two constructs: result demonstrability and visibility. *Result demonstrability* concentrated on the tangibility of using the innovation, including their observability and communicability. *Visibility*, on the other hand, focused on the physical presence of the innovation in the organisational setting. In the present study we are not concerned with teachers' perceptions of the Web as an IT innovation *per se*, rather we are concerned with teachers' perceptions of *using* the Web in two work-related contexts. We therefore use the instrument to separately examine teacher use of the Web for both *teaching preparation* and *teaching delivery*. The hypotheses tested in this study are:

Hypotheses: The seven adoption variables (relative advantage, compatibility, image, visibility, ease of use, results demonstrability, and trialability) will predict the dependent variables, teachers' future use of the Web for purposes of: (1) *teaching preparation* ; and (2) *teaching delivery*.

Data Analysis and Results

Multiple linear regression models were used to test the hypotheses. The unit of analysis was the individual teacher. The data was collected from one secondary school thus controlling for any between-school differences. All 75 teachers from the participating school were surveyed using a questionnaire that included the items from the short form of the Moore and Benbasat (1991) instrument. All questionnaires were returned and useable thus satisfying our sample size requirements and eliminating concerns of non-response bias. The questionnaire items measured teacher perceptions relating to each of the seven adoption variables forming the *independent variables* in this study. Two single item measures asking teachers about their intended use of the Web for (a) *teaching preparation* and (b) *teaching delivery* were used to measure the *dependent variables* in this study. All items were measured on a seven point Likert scale with polar anchors "strongly agree" and "strongly disagree". The Moore and Benbasat (1991) instrument has been used extensively in the literature demonstrating reliability and validity in a range of contexts. Tests for internal consistency reliability and construct validity provided strong support for the instrument in this study.

A multiple regression analysis (full model) was conducted of all seven ICT adoption variables on the dependent variables: (a) *Web use for teaching preparation* (TPREP); and (b) Web use for *teaching delivery* (TDEL). Tests were conducted to check the regression assumptions of normality, linearity, and homoscedasticity of residuals (Tabachnick & Fidell 2001). The tests revealed that the regression assumptions had not been violated.

Hypothesis 1: A multiple regression analysis (full model) was conducted of all seven adoption variables on the dependent variable *Web use for teaching preparation* (TPREP). The results indicate strong support for Hypothesis 1. The full model regression equation was statistically significant ($p < .0001$) and explained approximately 72% of the variation in TPREP (Adj. $R^2 = .718$). Model reduction techniques (Tabachnick & Fidell 2001) were then used to formulate a reduced model which included only the significant variables of relative advantage, result demonstrability, and trialability. The results indicate that the reduced model regression equation was statistically significant ($p < .0001$) and there was no significant difference between the full and reduced model in terms of their ability to explain variation in TPREP (Adj. $R^2 = .723$). In the reduced model, *relative advantage ($p < .0001$), result demonstrability ($p = .001$)*, and *trialability ($p = .012$)*, have a positive and significant relationship with TPREP.

Hypothesis 2: A multiple regression analysis (full model) was conducted of all seven adoption variables on the dependent variable *Web use for teaching delivery* (TDEL). The results indicate strong support for Hypothesis 2. The full model regression equation was statistically significant ($p < .0001$) and explained approximately 53% of the variation in TDEL (Adj. $R^2 = .531$). A reduced model was formulated that was statistically significant ($p < .0001$) and there was no significant difference between the full and reduced model in terms of their ability to explain variation in TDEL (Adj. $R^2 = .547$). In the reduced model, *compatibility* ($p = .003$), *visibility* ($p = .036$), and *ease of use* ($p = .006$), have a positive and significant relationship with TDEL.

The results also showed that *image* has a negative although not significant relationship with both TREP and TDEL.

Implications for E-Learning Diffusion

As hypothesised our empirical results show that DOI theory as operationalised in this study was successful in predicting the future Web use by secondary teachers for purposes of teaching preparation and teaching delivery. The most interesting aspect of the results was that in each of the two contexts of Web use by teachers three different factors emerged as significant. Of further interest to school principals is the fact that image did not emerge as a significant factor in either of the cases. This finding indicates that strategies that promote the status (or image) of teachers who are currently advanced in their use of the Web may not have any effect on the adoption behaviours of other teachers. Principals seeking to increase the rate of adoption of the Web by teachers should be better served adopting strategies that address the attributes of the Web found to be significant in this study. In the case of Web use for teaching preparation the three most important factors affecting teachers in our sample were relative advantage, result demonstrability, and trialability. This finding suggests that in the context of our sample, strategies to increase the diffusion of teachers' use of the Web for teaching preparation should specifically address these attributes. While in the case of Web use for teaching delivery, strategies should focus on the attributes of compatibility, visibility, and ease of use. The following discussion provides some examples of how this may be achieved in each case.

Strategies for Increasing Web use for Teaching Preparation

Relative advantage was concerned with the degree to which using the innovation is perceived as being *better* than using its precursor. The term *better* related to factors such as quality, efficiency, and effectiveness. Thus, one strategy to increase adoption in this context is to organise professional development programs that require teachers to prepare a lesson on the same topic (eg. The Solar System) using traditional methods followed by use of the Web. Teachers could then be asked to evaluate each lesson in terms of efficiency (ie. time spent), and the quality and effectiveness of the final lesson plan.

Result demonstrability represents the extent to which use of the Web provides teachers with clear, measurable, and observable results. In the case of teaching preparation the results are evident in the final lesson plan and the reaction of students. Therefore in the context of our sample, teachers should be encouraged to formally evaluate lessons that have been prepared with and without the utilisation of the Web. For example, a survey of student satisfaction at the end of each of these lessons may provide the teacher with greater insight and clear evidence regarding the results of using the Web when preparing lessons. In addition, principals could provide teachers with the latest research on student learning in technology rich environments.

Trialability represents the extent to which teachers can trial the use of the Web in teaching preparation prior to adoption. One strategy for increasing the trialability of the Web for teaching preparation is to provide teachers with convenient access to the Web in places where they are most likely to perform this activity. At school these areas would obviously include staffrooms, common rooms, and classrooms. It is also common for teachers to prepare lessons at home and therefore any scheme that subsidises teachers for the costs of Web access from home would increase opportunities for trialing the Web. Good quality peripheral devices, such as colour laser printers and screen projectors, should also be available for teachers to trial when using the Web to prepare lessons. Trial agreements with vendors of e-Learning related products and services could also be utilised to assist in this process. Finally, professional development sessions providing opportunities and advice for teachers to trial the Web for teaching activities would be beneficial.

Strategies for Increasing Web use for Teaching Delivery

Compatibility represents whether or not the innovation is perceived to fit teachers' existing values, needs, and past experience. In the context of our study, the move to teaching delivery through the Web represents a dramatic shift from the traditional face to face teaching methods familiar to most teachers. Organisational strategies will need to target this problem in order to increase teacher perceptions regarding the compatibility of this non-traditional teaching mode within their context. Teachers could be supported in this regard through professional development regarding the pedagogical implications of e-Learning. Radical structural changes may also assist increasing the compatibility of Web-based teaching in the traditional school environment. For example, school policy currently requires students and teachers to attend each class in the traditional mode, thus creating an inherent structural limitation for the diffusion of Web-based teaching delivery. That is, any Web-based delivery will be conducted over and above the existing face to face workload of both teachers and students. One organisational strategy to overcome this problem may be the rescheduling of the school timetable in order to facilitate a mixed delivery mode.

Visibility examines how apparent or visible the use of the innovation is in the organisation or school context. In the context of our sample, Web use for teaching delivery is a relatively more recent innovation than Web use for teaching preparation. At this early stage, increasing the rate of adoption of this innovation will require strategies that promote the physical presence of the innovation throughout the school. For example, vendors of Web-based delivery products could be invited by the school Principal to promote their products at staff meetings and most importantly provide sample content for teachers to access on the school network. Teachers in other schools involved in best practice in this area may also be invited to the school to share their experiences.

Ease of use is concerned with the ease of using, learning, and implementing the innovation. In the context of our sample, Web-based teaching delivery is relatively new to teachers and at this stage they may be unfamiliar with the technologies supporting this mode of learning. As such, the school Principal may adopt a number of strategies to assist teacher perceptions during this initial phase including increased time for professional development, the employment of competent e-Learning resource developers, and the provision of adequate user-friendly infrastructure to facilitate the implementation process. Another important strategic consideration is the identification and acquisition of existing e-Learning resources suitable to the teaching and learning context of the school. This process will allow teachers to build on existing modules thereby reducing difficulties of implementation.

Abstract: This paper presents the second phase of development of Computer – Based Simulation Laboratory (CBSL) for e-Learning especially for non-electrical engineering background. There were 14 lab sheets used in this study. Each lab sheet was divided into different components in order to help the students get used to the process of thinking properly. The steps of developing CBSL were as follows : 1) taking the students' opinions on CBSL (first phase) into account such as the correctness, and the completeness of the contents for making corrections on CBSL 2) design the computer program, and 3) get validated by 6 experts. The results of the study were that most of the experts were satisfied with CBSL at the good level particularly on the picture/image. However, there was still a need to improve the contents, and others. After all, CBSL was developed on CDR which introduces to the undergraduate students the engineering way of thinking. The computer-based simulation experiments were developed for beginners in science and engineering. Its objective is to facilitate students to experiment, solve problem, gather data, and to engage scientific interpretation in the early studies.

Introduction

What is engineering ? The word itself comes from the Latin word *ingenerare, to create*. It's art and communication, politics and finance, modeling and simulation, invention, approximation, measurement and estimation, and more. It's a way to think about problems. The laboratory is an important component of the lecture where students gain hands-on experience. Thus, to introduce the engineering student the way of thinking is to develop a *Virtual Laboratory*- a set of simulated laboratory experiments that we can perform over the WWW (Karweit, 2001). With the development of new computer technologies, the World Wide Web is now possible to simulate engineering and science laboratory projects on a computer. Computer lab activities such as pre- and post-lab exercises, can help support varied approaches to electrical education (Yaron, 2002). Experiences in laboratory experiments are difficult to provide in typical classroom settings because many interesting physical artifacts are expensive or dangerous to build and practice on. However, Computer-Based Simulation Laboratory (CBSL) will address these problems cheaply and safely. It will also provide coaching for students, in order to help them understand fundamental principles, to help them practice the skills needed to analyze, and to provide the kind of supervision that a good laboratory assistant provides by way of minimizing unenlightening aspects of student explorations (Forbus, 1999).

Findings

The study involved the steps of CBSL development as follows:

1. Design the components of CBSL as follows: 1) Lab Sheets, 2) Instructions on how to conduct physical labs, 3) Step by step guide through experiment 4) Analysis, and 5) Report Writing.

2. Select 14 labs for CBSL development according to the students' opinion particularly on the correctness and completeness of the contents (Jitgarun & Tunlasakun, 19-21 October, 1999) as follows:

2.1 *Compound Motor Laboratory*

A student will be able to adjust Variac, R1 and R2 easier than the real experiment and the output response can be seen promptly and clearly. The color of motor while spinning will stimulate the student's interest in doing the experiments.

2.2 *Series Motor Laboratory*

A student will be able to learn how to connect the circuit for series motor. Then, while adjusting Variac and R1, it is possible to make note of the starting point of the current to be six times while it is running.

2.3 *Shunt Motor Laboratory*

A student will be able to learn how to connect the circuit for shunt motor. Then, while adjusting Variac and R1, the starting point of the current will be six times while it is running.

2.4 *Alternator Laboratory*

A student will be able to adjust the load so that the loss and efficiency of DC Generator can be found.

2.5 *Induction Motor Laboratory*

To connect the control circuit and to test the circuit operation by pushing an *on-off* button, it will help move the motor in a clockwise or anti clockwise direction and/or using on-off lamp.

2.6 *DC Generator Laboratory*

A student will adjust R1, R2 easily and precisely and be able to observe the graphs. A student doesn't have to plot the graphs by him/herself. The colors of the graphs, the motor while working, the primover and the loads will help the student see the steps of operation clearly. This is how it can stimulate the student's interest.

2.7 *3 Phase Rectifier Laboratory*

The circuit will be 3 Phase Half Wave Rectifier. A student can adjust input voltage and graphs will be changed accordingly. Then, all of these graphs can be zoomed in and out. Thus, simulation will be safer for a student as well as the equipment. The different colors will help a student see the signals of different phases clearly.

2.8 *3 Phase Measurement Laboratory*

A student can adjust Variac or push the on-off button to show electrical power output and electrical current value in graphs and/or by the on-off lamps.

2.9 *Single Phase Rectifier Laboratory*

A student can adjust voltage input and observe the changes of voltage output of rectifier circuit which will be shown in graphs.

2.10 *Single Phase Transformer Laboratory*

A student can adjust Variac along with the changes of Volt meter and Amp meter simultaneously. The simulation of virtual lab will be safer for the student as well as the equipment while there are on-off loads and short circuit. It also motivates the student to do more experiments because it will show on-off lamps. However, when over current, there will be a warning with a dialogue box.

2.11 *Single Phase Measurement Laboratory*

A student can push on-off button and observe the changes of Volt meter, Amp meter, Kilo-Watt meter, KiloWatt-hour meter of which the load can be changed accordingly.

2.12 *3 Phase Transformer Connection*

A student can select secondary voltage at 127 V. or 220 V. and observe the changes of Volt meter, Amp meter of each phase.

2.13 *Star-Delta Laboratory*

A student can push on-off switch, setup time delay, and observe on-off lamps when time is over. Then, a student can also see output in the Amp meter as well.

2.14 *SCR Rectifier Laboratory*

A student will be able to adjust Vs (Supply) and Trigger Angle easily, precisely, and be able to see the changes of signal outs that takes place from Vs (Supply) and Trigger adjustment. What's more, the input and output signals are comparable to one another at the same time.

3. Design simulation kits on the computer screen.

4. Construct simulation laboratory instruction with Borland Delphi program, Adobe Photoshop, Visio Technique, and PSpice.

5. Develop the manual for CBSL.

6. Trained experts check for the accuracy which were as follows:

The responses of six trained experts' satisfaction upon CBSL were found to be at the good level with the pictures/images. The synchronous of the contents and their objectives, the simulation capability, the order of the contents, the promotion of thinking process, the convenience, the safety and the fastness were identified at the good level while the accuracy, the completeness, and the promotion of thinking rather than remembrance were still rated at the average level.

Discussion and Conclusions

As the results of the study on Computer-Based Simulation Laboratory (CBSL), the researchers would like to discuss and conclude as follows:

1. Technical educational institutions are crunched between demand for an effective education along with budget constraints. Their ability to deliver effective education can be greatly enhanced by laboratories equipped with modern technologies including computer hardware and software capable to perform data acquisition, statistical data analysis, control experiments, remote instrument control and network communication (Ursutiu, 2002). However, there are some problems in providing experimental instruction as follows: 1) Inadequate equipment and tools matching with the number of students, 2) High number of students in a group, 3) Insufficient teaching time, 4) Out of order equipment and tools used during the experiment, 5) Damage of equipment and tools used during the experiment, 6) Danger of the mistake in experiment for the experimenter, and 7) Too much time used in equipment and tools in the real operation.

Thus, CBSL is an environment in which the students may make *authentic* actions and receive *authentic* responses from the *virtual* equipment (Virtual Laboratory, 2002). There is no additional equipment besides the computer, monitor, and mouse necessary for this type of experience. A teacher creates CBSL where students can conduct experiments that they would otherwise not be able to do because the equipment are too expensive. Experimental results indicate that students who use CBSL prior to conducting the same experiments in a physical laboratory are able to complete the physical laboratory in a much shorter time, require less assistance, and also report that they are very satisfied with their laboratory experience (Mosterman et al., 2002).

2. Engineering sciences and physics education have always been dynamically interrelated with technology change. By solving control problems using software-based instruments and actual hardware, students gain an appreciation of the interaction of process instrumentation and computers. The interaction of instrumentation and networked computers running graphical software reduces manual data collection, analysis, presentation, storage, and transmission tasks, allowing supplemental material to be covered by the professor in the same time span.

3. "…there will be more CBSL in the future. Perhaps five years down the road, one-third of the experiments may be done virtually. However, the CBSL are not established to replace face-to-face teaching, but allow the students to carry out the experiment before or after the real session" (Ko, 2002). Pre-experiment *hands-on* experience for students before they go to the actual laboratory (Zhu,1997). A teacher has his students use CBSL as a pre-lab so that they can understand the basics of the lab before they actually do it. Thus, CBSL can only augment the lecturers' teaching tools. It can't replace them. While the results of any education are difficult to prove, sufficient evidence exists that CBSL provides a fresh and fun way to supplement traditional education. Though CBSL cannot replace traditional education in many tasks, it may be better than traditional education when used appropriately (VirtualChicago Project, 2002). Computers aid students in laborious data-logging and enable them to perform extensive experiments. Many of the students spent as much time modifying their CBSL as they did on the experiment. It should be emphasized that CBSL is not intended to replace the hands-on laboratory inquiry but to extend it into investigations that are not feasible in the classroom. As CBSL develops and more options become available, student inquiry will become more and more open.

4. Once CBSL has been set up, students or users will be able to conduct actual experiments from remote computers anywhere in the world twenty-four hours a day, as if they were working in actual laboratories. This technology greatly enhances the flexibility of laboratory education, and introduces

students to the new paradigm of remote experimentation (Ko, 2002). The term *CBSL* refers to any learning process that takes place in virtual reality, or a virtual classroom. The location where learning takes place is called *virtual* because it does not exist in reality. Since CBSL is a non-traditional form of education, students and educators should be prepared for different forms of learning.

5. Creating articulate virtual laboratories requires synthesizing advances involving several technologies such as *Qualitative physics* which provides formal representations for the tacit knowledge of scientists and engineers that connects their professional knowledge to their experience-based intuitions, enabling software to use methods and concepts similar to those deemed natural by domain experts;. *Compositional modeling* provides representations and reasoning techniques for computer-assisted modeling (e.g., how to apply professional knowledge of a domain to modeling real-world situations so that they can be formally analyzed); *Truth-maintenance systems* provide reasoning services and the raw material for constructing explanations of the system's results and reasoning in terms that help students understand the domain of study; *Symbolic algebra and constraint propagation* provide mathematical solutions; and *Analogical processing techniques* provide the ability to retrieve and apply results from libraries of worked out designs and examples to novel situations, in order to coach students (Forbus, 1999).

Modelling a Web-based Learning System using Wired and Wireless Technology

Jun H. Jo, Vicki Jones, Greg Cranitch and Kyung-Seob Moon
School of Information Technology
Griffith University, Gold Coast Campus
QLD Australia 4217
{j.jo, v.jones, g.cranitch, k.moon}@gu.edu.au

Abstract: Internet technology has been rapidly developed and had a significant influence on education. However, through implementations, online teaching systems have not shown sufficient flexibility, which is the key element to this new approach. The current use of wireless technology has triggered attempts to inject greater flexibility into e-learning. This paper will propose a new model incorporating wireless technology within an e-learning system. The integration of the new technology in the current hybrid system will be discussed. The system will employ Pull/Push technology to provide efficient communication between educators and students.

Introduction

A number of universities around the world have attempted to use Wireless Local Area Networks (WLANs) in order to provide learning environments with sufficient flexibility. However, the cost of establishing a WLAN system is significant and the flexibility is usually accomplished within the proximity and operational area of a connection point. By including the benefits of wireless technology, this research investigates a new e-learning system with greater flexibility, regardless of time and location. The new Wireless Web-Based Instruction (WWBI) system will integrate a mobile phone and a Personal Digital Assistant (PDA) within an existing online teaching system which has been developed and used at Griffith University in Australia since 1999.

Wireless and Mobile Technology

Wireless Application Protocol (WAP)

WAP was designed to handle the limitations of wireless networks, such as narrow bandwidth, and unstable and unreliable connections. The WAP forum set the specifications for the micro-browser requirements in mobile and wireless devices (Moon, 2001). A micro-browser, as defined by the WAP specification, is the ultimate thin client. In a handheld device, it can operate with a small amount of memory, which suits the limited resources of the device.

The proposed system is designed to deliver teaching materials using:

- Protocols: HTTP and WAP
- Markup languages: HTML for multimedia information and WML for simple text message
- Communication methods: *pull/push*

Wireless Markup Language (WML)

Although HTML is a relatively simple markup language it is still too complex for use with a WAP device. Because of the constraints associated with handheld devices, an alternate model was necessary and WML was developed in 1999. WML and WMLScript (an event-based language, based on JavaScript) provide the functionality needed to reduce the load on the CPU. As a result, WML is a highly simplified markup language, which follows strict XML specifications (Bulbrook, 2001). Like HTML, the use of WML allows designers to specify format and presentation of text, and control navigation through a series of hyperlinks between pages.

Pull/Push Messages

Currently WBI systems are based on pull technology, which means that users request, or pull, information to their handheld device. However, using this method, when information perhaps of an urgent or otherwise important nature needs to be sent to the user, it will not be received until the user logs in and requests information. An example would be: when the university needs to inform students of a change or cancellation of a lecture. The new elearning system will allow students to be contacted by both educators and other students, using pull/push technology. The pull/push technology (see Figure 1.) in the new system can provide an efficient way to transmit information.

The concept of pushing and pulling information is not new. It has been used in the finance industry for some time, in the form of financial paging services. Information is pushed to the user's pager. The user can then pull more information from the website or from call centres. However, in reference to WAP, Push (or WAP Push as it is sometimes called) is slightly different. Using WAP Push a notification message can be sent to the user, who can then pull more information using links embedded in the message. It is made easy to use by allowing the user to just click a button to go to the WAP site (Bellis, 2000).

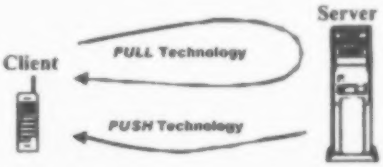

Figure 1: Pull and push technology

Personal Digital Assistant (PDA) Technology

Although some PDAs come with a small keyboard, PDA technology does not require a keyboard, and PDAs also come with a touch sensitive screen operated by a special input/output pen. The built-in graphical interface of a stylus-operated PDA uses both touch-pad technology and handwriting recognition, which allows the user to "write" on the small screen with the stylus pen. Some of the keyboard PDAs also have a pen and touch sensitive screen (Moon, 2001).

The advantages of PDA technology include:

- Convenience – easily accessible when needed
- Portability – easy to carry, small and light-weight
- AT/AP – easy to use the Internet anytime/anyplace
- Ease of use - management of personal information and tasks
- Display screen - generally reasonable and functional in size (capable of displaying thousands, or millions, of colours)
- Extra features - entertainment such as games and music (often includes MP3 and mpeg4 players)

The constraints (disadvantages) include:

- Limited battery life
- Limited CPU power
- Still relatively expensive – although prices will come down
- High running costs

Many PDAs include a wireless communication module, but if not, a mobile phone can be used as a wireless modem for data communication. There are three common methods of data communication: IrDA (Infrared Data Association - inexpensive with high transfer rates; Bluetooth (currently the most common communication method used in wireless communication) and RS232C serial cable (easy to implement, inexpensive, with lower distance limitations than parallel communication). These methods are also used to provide connection between PC and PDA.

Wireless Technology in Education

In the university environment the mobile phone is a common device for both mature-age and younger students. Yet there are significant limitations when using the mobile phone as a WBI device, such as: small screen, limited method of input, and lack of multimedia functionality. The new model aims at employing PDAs to overcome the limitations of mobile phone use.

Some of the promising aspects of wireless technology in e-learning include:

- *The rapid growth of mobile phone use:* There is an estimated 600 million wireless phone users worldwide. This exceeds the current Internet user base of about 420 million, of which 10 percent use wireless Internet (Bulbrook, 2001). The population of mobile phone users provides a significant infrastructure for wireless technology in e-learning.
- *Flexibility:* Many of Australia's tertiary students have part-time jobs, so flexibility is a key issue. However, on-line teaching cannot presently provide all the possible benefits of AT/AP. Wireless technology has the potential to enrich flexibility and offer significant increases in the number of resources available to students.
- *Easy Access:* Wireless e-learning may be an attractive alternative to attending face-to-face learning environments, especially in large metropolitan areas which suffer traffic congestion and lengthy commuting times.

A Hybrid System Model

The hybrid system provides two methods for students to access the main server:

- The use of a networked desktop/laptop PC
- The use of a mobile phone and a PDA

Figure 2 shows the Hybrid System Model. There are three main sections: Students, Mobile Base Station and Service Centre Module.

Students: Students can access the main server using a networked PC either from home or from the university's computer lab. From the computer lab, students generally have access to fast connections, with large memory and large computer screens, compared with access from home. Unless the student has broadband access the connection speed will be considerably lower than using this method. Therefore, to cater for all aspects of the learning environment, the learning materials are not only in text and picture formats but also in multimedia format such as movie, animation or real-time video streaming. The new model uses the online teaching system that Griffith University has developed and used since 1999 (Jones, Jo and Cranitch, 2000). This process is based on the Pull method for HTTP information.

Students can also access the system using a mobile phone and PDA. This feature aims at improving the flexibility of the system. Students can access the main server through the WAP gateway and browse the concise textual information such as: a Table of Contents (TOC), which includes teaching materials and MSN messages; and a Notice board (from educator or the university).

Push technology is used here and information is written in WML using WAP. When the student finds the required information in the TOC and wants to access it, the PDA can be used to display the information in either WML or HTML. This is especially suitable if using multimedia format. The mobile phone can be used as a modem and the PDA as a multimedia device.

Mobile Base Station: The Mobile Base Station is responsible for providing wireless connection to the student module as well as the wired connection to the service centre module. A mobile communication company provides this service.

Service Centre Module: The Service Centre Module shows the gateway, an ISP server and the University Web server. The *WAP gateway* is positioned between the Mobile Base Station and the University Web server. Its job is to transfer information via WAP and HTTP. When students use a PDA with a mobile phone as a modem, the format will be HTTP and does not need to go through the gateway. The use of various expansion cards enable PDAs to access the server or a Wireless LAN. Some expansion cards can also make a PDA act as a mobile phone. However, our system aims at all types of PDA and does not require any special expansion cards. The *ISP* server is the link used by students accessing the university server from home. It consists of a separate, possibly private, company that supplies Internet hours to the students. The *university server* is the main server holding all the data available for the educational learning module.

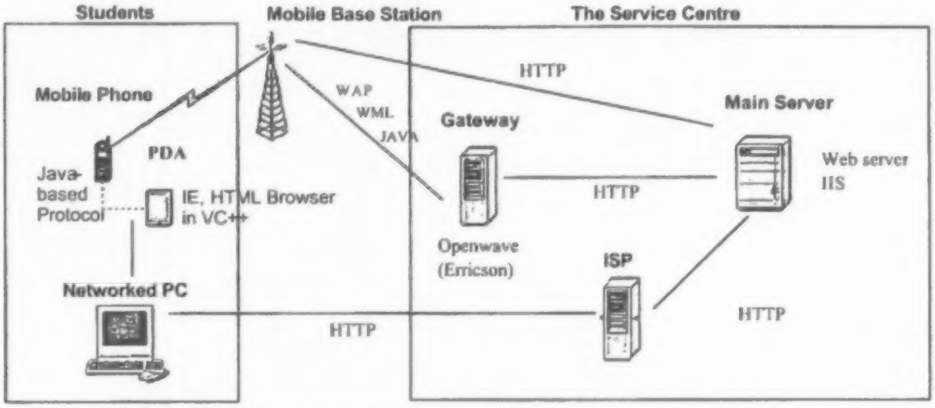

Figure 2: Hybrid System Model

Conclusion

This paper introduces a Hybrid Delivery System, which includes both wired and wireless technology. The aim is to provide the general online delivery system with more flexibility and to improve the student-learning environment. To overcome the limitations of using a mobile phone, the system has employed the use of PDA technology to provide a larger screen, improved computational functions and increase storage capacity. The new system will adopt *Pull/Push* technology to provide efficient and economical communication between educators and students. Currently, the wired part of the system is complete and is being implemented. The *Pull/Push* technology has been developed and emulated using Openwave and will be applied to the teaching environment in the near future.

Developing Web-Based Materials for Electronic Learning

Background:
The eMath initiative is one of the first national efforts to create and deliver innovative multimedia instructional mathematics developed by middle school mathematics teachers.. eMath meets state standards for middle school math through its development of state-of-the-art, customized program that changes fundamentally how teachers use multimedia and web-based resources in middle school mathematics classrooms. In particular it has looked to fundamentally change how middle school teachers teach mathematics and how teachers and students engage in the learning process.

Partner schools from seven rural, small school districts in East Texas teamed with the parent company of eSchool Online, ACTV Net, Inc., to produce 30 mathematics modules (10 per grade level) and three staff technology staff development modules that target student learning in identified areas of student high need and teacher professional development. The program uses blended technologies such as video, web-based material, collaborative exercises and imbedded assessment. The math content is being delivered through eSchool Online software optimizing the Internet to deliver not only instructional material but also professional development to approximately 8000 students and 85 educators (teachers, math specialists, administrators, and library media specialists).

Aspects of the Initiative:
The impact of this initiative is felt by teachers and students moving toward an engaged learning and problem based learning model. Each teacher accesses the curriculum through 30 interactive modules delivered on demand via the Internet. This integrative web portal provides for email, program resources, teacher administration, instructional and unit development and a proven project based learning model. Videotapes clips using real life situations are used to demonstrate the mathematics concepts. Module development is targeted toward Texas State performance standards Math objectives 9, 11, 13 as well as the development of algebraic concepts. Students and parents access the modules from their school libraries, classrooms, computer labs, public libraries, ad hojme computers.

Also a select group of 14 teachers have been involved in the development of all the materials through inception to completion. Middle School mathematics teachers were developers of the content of the discovery based materials, its formatting and presentation style. Working with and through math experts from across the state the teachers developed the materials and took enormous ownership in the project. All materials were matched to the instructional learning styles of middle school students and were scrutinized for appeal to all ethnicities and gender.

Presentation information
Initial first year data will be presented. Research questions that will be addressed from data collected from school district administrators and eMath middle school teachers are:

a) what types of changes in thinking about mathematics pedagogy have teachers had since beginning the development of these materials; b) has the interaction between teacher and student changed since beginning this initiative and if so why; c)hat types of skills do classroom teachers need to have to develop online materials; and d) what is it or what was it that significantly changed the way you taught mathematics?

The Technology Mentor Fellowship Initiative: A Study of Cross Generational Learning

The Need

Our fast moving world expects educators to prepare students and teachers for needed future skills, including technology application, which have been underused to date. The current focus of technology in education has moved to curriculum integration and practical uses of the technology to support e-Learning, rather that the former focus of computer skills and isolated application instruction. This change, along with continual change in technology, impacts education directly and requires innovative ways to deliver instruction. Not only do we look to innovative ways to deliver curriculum but we also look for innovative ways to develop preservice teachers who are well versed in technology and its use and who are confident with technology integrations (Elwood-Salinas, 2001; Macers, Browne, & Cooper, 2000; Gillingham & Topper, 2000' Stuhlmann & Taylor, 1999).

The design of this initiative, funded by the US Department of Education, is to address the need for increased faculty proficiency in technology while recognizing the challenge and the potential of the disparity between faculty and students in technology skills. The goals of the project were to facilitate faculty development through both approaches: building capacity and providing tech support. This was done by: 1) developing proficiency of the faculty in the Texas A&M College of Education (COE) in the use of various instructional and communication technologies (building capacity); 2) developing capacity within the Texas A&M COE in digital media that supports the NCATE standards and the International Society for Technology in Education (ISTE) (building capacity); and 3) providing support to faculty transitioning to the new teacher training program by providing support in the area of technology support and infusion into the curriculum and coursework (providing tech support).

Program Description

The Technology Mentor Fellowship Program (TMFP) draws upon successful strategies evolving from programs funded by the Technology Literacy Challenge, specifically the Generation www y program, Gen Y Challenge Grant-Olympia, Washington) and the Profiler and Trackstar tools developed in a partnership with the current High Plains Regional Technology in Education Consortia. Training materials supplied through a partnership with Intel and Microsoft (Gates Foundation) through the Intel Teach to the Future initiative provided additional training and support.

The scope of work for the TMFP is to: 1) Provide teacher education faculty (campus based faculty, cooperating teachers, early experience supervisors) a system for technology training that:

- Provides intensive mentoring and support to faculty, and cooperating teachers in the field from pre-service teachers experienced in the process of integrating technology into instruction at the K-12 level;
- Identifies the growing knowledge base within college and school organizations, among students and faculty, and supports the sharing of both skills and knowledge through collaboration and the development of specific, skill related instructional objects;
- Provides continuous assessment of competence for college and school teacher education faculty, in the area of integration of technology into instruction;
- Provides professional development activities tailored to the particular needs identified by teacher education faculty regarding technology skills/processes for technology integration.

2) Provide teacher education faculty and pre-service teachers access to a repository of instructional objects designed to:

- Develop and use basic technology skills, skills in the instructional application of technology;
- Use technology -congruent pedagogy, such as project based learning and continuous skills assessment;
- Be searchable by their application to specific issues related to the integration of technology into instruction across grade levels, content areas, and national standards.

3) Provide opportunities to organize instructional objects into web-based courses.

Findings

Findings from this study not only address issues related to intergenerational learning and cross-age and cross-gender teamwork but also issues related to organizational change to support technology utilization and faculty change regarding pedagogy used in their classrooms.

- Why use a technical assistance group that ranges in age from about 18 to 24 years of age? First we know that this age group is made up of predominately the Net Generation (sometimes called Generation Y). The Net Generation, having grown up with the new technologies, enters our institutions of higher education with a much better comfort level for technology than the existing university faculty who grew up with television and radio. Consequently an "Intergenerational Digital Divide" exists.

- To compound the problem, a second divide exists in our state: that is, the technology infrastructure gap between public schools and higher education teacher preparation programs in Texas. Texas schools have experienced substantial technology infrastructure changes over the past few years. Colleges of Education, however, are limited in their ability to provide substantial pre-service training in Internet-based technologies so that beginning teachers may take advantage of this increased infrastructure. Rather than presenting exemplary models of technology-enhanced instruction to pre-service teachers, most Texas institutions of higher education are struggling with integrating technology into courses and content areas and in offering of on-line courses.

- Certain structures must be in place organizationally to begin, support, and sustain, technology infusion. These beginning structures consist of such things as support from the Dean and support from each of the Department Heads in the COE. This support cannot only be in the form of verbal support but must also come in the form of monetary support to sustain the technical assistance structure. Included in the organizational structure for technology integration should be a system for rewarding faculty that achieve a certain level of expertise and then model that level of expertise in their teaching. Also in this organizational structure should be a plan to fund the technical support.

- To successfully utilize technology in their teaching situations university faculty must have a certain level of expertise and comfort with the technology. They must have a certain level of "executive control." That is faculty must be able to do particular technical functions without really having to think much about it and must be able to then understand its transferability to their teaching situation.

- Teaching with this new medium has drastically altered the role of the teaching faculty requiring a group, or team effort. When implementing technology we must involve numerous specialists including instructional designers, graphics and multimedia designers, and programmers. Few faculties have the time or enthusiasm to integrate technology without a support team. This support team should provide "just-in-time" assistance to the university faculty.

- In addition to learning to work as a member of a team, instructors may need to change their pedagogical approaches to teaching and learning, moving from being the presenter of information to a facilitator of learning.

- The COE should have a mechanism in place to assess educational technology competency for its preservice students. A number of assessments are on the market to do just this. When deficiencies are found then technical support must be provided to the preservice student either in the form of access to an educational competency course or individual technical assistance.

- Provide in-service teacher mentors to our preservice education programs. These K-12 mentors could provide ideas for collaborative project development with K-12 institutions and institutions of higher education.

Writing for the Web

David Kim Juniper
Educational Media Development
Athabasca University
Canada
davidj@athabascau.ca

Abstract: The purpose of this brief paper is to explore how the World Wide Web differs from print and to give educators the tools they need to write effectively for this new medium. Topics covered range from paragraph length and sentence structure to fonts and the importance of a minimalist approach. As more educational institutions move their materials online and on CD-ROM, and more students expect digitally-based instruction, instructors are faced with a serious challenge. The first step in putting any written materials online is ensuring that the material is presented in the most usable way possible. As the pioneers of online education, it is up to today's teachers to forge a path that others will follow.

The World Wide Web is rich in pedagogical opportunity. As more educational institutions move their materials online, and more students expect digitally-based instruction, educators are facing an increasingly serious challenge. Unlike print, which has an established history and clear guidelines for its production, online materials are very recent and demand a different approach. Where do we, as educators, go from here?

The first thing to consider when placing educational materials online is the manner in which these materials will be read by the student. Are the materials intended to be read off the monitor or will they be printed by the student? This distinction is of paramount importance, and will inform the manner in which the materials will be presented, the structure of the document, etc. In the next few paragraphs, I will explore these two approaches and highlight the major aspects of each.

The "print" strategy involves using materials to be printed off and read at a later date. This approach will likely be the most familiar to many educators, as most of us have been trained in the print medium and are familiar with its conventions. As with most print-based material, the student will be expected to follow a linear approach to reading the printed document. Online students will navigate the text by scrolling and by using internal links, such as the "back to top" links often seen in longer html documents. Appropriately structured paragraphs and sentences give a sense of coherence to the material and maximize student understanding and retention. The document should be single-spaced, with a double space between paragraphs to enhance online readability.

Sub-headers assume a high degree of importance in longer documents, as they play a major role in its navigation. Using internal links, students can access individual sections of the document through a "Table of Contents" often found at the top of the page. Using the "Print Selection" option offered by most browsers, the student may print out sections of the document instead of the entire document.

Before continuing on the next online strategy, I'd like to take a moment to discuss the use of fonts online. Although a discussion of online typography could easily fill an entire paper in itself, I would like to touch on a few fundamentals with regards to usability. The default font used on the World Wide Web is Times New Roman, a font designed for both legibility and economy of space in the print medium (Bernard et al. 2002). Conversely, according to Ramsden (2000), the most widespread sans-serif font used on the World Wide Web is Arial, which also has a history based in print. The widespread use of these fonts online should not be mistaken for a "best-practice" however, as these fonts have since proven themselves less than efficient when read online.

Among the many alternatives to both Times New Roman and Arial, many designers and usability gurus have chosen either Georgia (serif) or Verdana (sans serif) as the best choice for online text. In an article in *Cre@te Online* magazine, Stuart Dredge describes how the low resolution on the monitor screens (72 dpi as opposed to 2400 in print) can play havoc with the readability of many print-based fonts. Options such as Verdana and Georgia come up winners because they were designed primarily for the monitor screen. In the following example, taken from a web page, you will see the differences between the fonts.

Times New Roman

Arial

Verdana

Georgia

Moving on from the world of print, the other approach to using the Web, and the one which poses the greatest challenge, is material intended to be read from the monitor itself. In addition to choosing the right font, the educator is presented with a host of other design challenges. Unlike traditional readers, the student who is reading online text is always on the verge of going elsewhere. The Back button, the Favorites or Bookmarks menus, all beckon the student to other digital destinations. The challenge then becomes how to capture and hold the student's attention.

There are a few core rules to follow when creating online materials designed to be read online. The foundation upon which these rules and guidelines rest is the fact that students rarely read online materials - they scan them (Nielsen 1997). Rather than reading the entire text in a linear fashion, online users are more likely to jump from paragraph to paragraph, searching for the main ideas or concepts they recognize, or stopping in areas which arouse their interest. Furthermore, because of the abbreviated attention span of many web surfers, large blocks of text are likely to be quickly discarded in favor of shorter more compact fare. To overcome these challenges, effective online text usually adheres to the following guidelines;

1. Keep the lines short. The flickering background of a computer monitor makes reading more difficult, so each line should not be longer than 10 - 13 words.
2. Short paragraphs of 150 words or less help ensure readers stay on task.
3. Make ample use of headers, sub-headers and bulleted lists.
4. Use the active voice rather than the passive
5. When appropriate, use different media such as images, animation as well as audio and video intermixed with the text.
6. Stay clear of cultural references that might confuse foreign students.

The aim in using the aforementioned guidelines is to create pages that will catch the reader's attention and maintain it. Much like journalistic writing, web writing makes good use of the snappy opening line, short paragraphs and sub-headers. Furthermore, web writing also often make use of the "inverted pyramid" strategy (Nielsen 1996). Starting the text with the conclusion, followed by the most important supporting information, ensures that the reader gets the most important parts of the article right at the beginning. Should the student desire more information, a hypertext link would lead to a more comprehensive treatment of the material which could be printed off and read at a later time. So, in this way we have the two strategies - read online and printed off - working together to provide the student with a quick, efficient online experience.

The Web is in its infancy, and will grow into a powerful force in education. As the pioneers of online education, it is up to today's educators to forge a path that others will follow. Simply transferring print-based materials directly to the Internet is not a viable solution, for different mediums have different requirements. By being aware of the idiosyncrasies and challenges of the online medium, educators can make a smooth transition to online learning and thus make full use of this powerful new pedagogical tool.

Teaching or Producing?
Orientation and Motivation of Virtual University Team in the Development of Web Courses

Kirsi Karjalainen & Esko Kähkönen
Educational Technology Centre
University of Joensuu
Finland
kirsi.karjalainen@joensuu.fi
esko.kahkonen@joensuu.fi

Abstract: In this paper orientation and motivation of the Eastern Finland Virtual University Network content production team is studied. Based on a questionnaire, in analysis applying content analysis, the goal was to detect factors affecting understanding and realization of the process of developing web courses. A special attention was paid to the question of understanding the task as production or teaching. The survey shows that the team understands elearning as additional element in teaching, with new insights to the development of teaching. Awareness of pedagogical approaches was low, but respondents were in fact intensively looking for models for more interaction, collaboration, better tutoring and self-directiveness of the student. The production of the web courses was rewarding for the members of the team, especially for those with teacher experience. Small scale production model, where any member of the group was familiar with various tasks in the production process, in supervision of the teaching institution, was a garant for didactic consciousness, and after the first phase of course production team members saw the very importance of careful planning that in the beginning was somewhat neglected.

Introduction

The purpose of this presentation is to study and analyse orientation and motivation of the Eastern Finland Virtual University team in the development of web-based courses. A special accent is going to be given to the matter, how the professional members of the group comprising of fourteen instructional designers, teachers and technical supporting staff, stand to central issues affecting e-learning. Those are the background and attitudes of the team, grade of virtual learning in study courses, pedagogical approach, infrastructure and support services, and quality of learning. Special attention is going to be given to the question whether the virtual university personnel considers their task more from the point of producing digital study materials or adding to the traditional way of teaching.

Background

The Eastern Finland Virtual University Network (EFVU) started up at the beginning of 2001 as part of the Finnish Virtual University (FVU), financed by the Ministry of Education. The program is linked to the national ICT-strategy (Education, Training and Research in the Information Society 1999). In the content production team of the EFVU work around 15 persons in the fields of Computer Science, Applied Mathematics, Environmental Technology, Business Administration and Economics. Around 60 credit units /study weeks of web-based courses are being produced in the team.

The Study

In June 2002 a survey was conducted with the purpose to discover experiences and orientation of the virtual university team engaged in the development process of web based learning in the EFVU. Fourteen persons working in different areas of expertise and in technical and pedagogical support answered the questionnaire, most of them in a seminar intended for the team of the EFVU. Those unable to attend the seminar filled in the questionnaire afterwards. The questionnaire was submitted to contents analysis, but also some basic quantitative methods were applied. In the team there are experts from subject departments of the universities and from the Learning / Educational Centres. Nine out of fourteen persons represent subject departments and five these support units. At least some background as teacher do have six persons of the team.

Findings

During the first half of the three-year Eastern Finland Virtual University Network -project, half of the respondents, including both teaching staff and support persons, have produced web-courses carrying the main responsibility. Before the project of Eastern Finland Virtual University Network over one third (n=5) of the respondents had gained experience in web-course production, most of them in more than six courses. Two of this group had produced web-courses having the main responsibility of the production process. A clear majority of the respondents were familiar with various roles in the production of web courses.

The respondents' involvement in the development of e-learning was mainly due to the fact that web-course production was included in respondent's job description and respondent's own enthusiasm for web-course development. The next important motives were person's interest in pedagogy and ICT.

All the respondents consider web-course production very meaningfull or meaningfull. The respondents with a background as teacher (6) considered course development very meaningful (5/6), those in supporting activities somewhat less (3/8). Odd, though, that persons with teacher experience gave as the most important reason to their engagement in e-learning, their job description or order of the head of the department. On the third place was given the will to develop teaching. The reason to this order of importance is not clear, if general obedience or dependence on institutional structures, on the other hand, in the case of a new learning culture, a certain mental dependence could be an asset for the teacher himself/herself; as he/she knows to work on behalf of the Institution. [See Table 1].

In the light of the above it is, though, an interesting point that persons involved in e-learning before the project period of the EFVU, were strongly motivated and directed by their own enthusiasm, whereas persons without early experience placed almost to the top the duty character of their role in the development of e-learning. These persons are mostly the teachers of the team, as described above.

Interest in pedagogy *and* technology were in the group of persons with previous experience (n=5) even, almost at the top of the appreciation, whereas in the group of persons without previous experience (n=9), interest *either* in pedagogy *or* technology was not decisive at all (ranking 4-5). In this group pedagogy got just three mentions altogether, and just the place five on the list of seven factors. Considered that the group of team members without prior experience was greater than that with experience, the figures show a clear accent.

	Persons with previous experience (n=5)			**Persons with no previous experience (n=9)**		
	Mentions	*Range*	*Order of importance*	*Mentions*	*Range*	*Order of importance*
An order of a superior	1	8	7.	3	1-2	2.
Own enthusiasm for web-course development	5	1-3	1.	6	1-3	3.
Web-teaching is "trendy"	1	5	5.	1	4	6.
Previous experience in audio-visual production	1	6	6.	0	0	-
Web-course production included in job description	2	1-7	4.	6	1	1.
Interest in pedagogy	5	1-3	2.	3	2-5	5.
Interest in technology	5	1-4	3.	7	2-4	4.

Table 1: Reasons leading to engagement in web-course production.

The respondents assessed they have very good or good ICT-skills in creating and editing www-pages, in integrated use of different programmes (eg. text transfer) and in WebCT, which is the standard platform in the institutions of all team members. Skills in transferring video into the net and video editing were most often considered fair or poor.

Text is the most often used and most valued web-course tool. There are no differences between teachers and supporting staff in this place. Text is for them informative and available and readable with technical solutions of low level. Discussion, when related to the subject, enhances the learning process. It provides with social connections, which were considered very important in a web-course. Tests were appreciated as self-evaluation tools. Animation was considered informative and illustrative. Video was still quite little used and appreciated, due to technical limitations and lacking expertise.

As the most important advantage of a web-course was considered the possibility to study over distance and time. This enables eg. personal learning schedules. Diversified material can be included – if there are enough resources for production. Other advantages mentioned were the possibility to use experts from outside and to insert illustrative elements to a course (eg. animation, photos, video etc.)

The respondents rank very high the possibility to personal learning style and offering tutoring to the students, regardless of the respondents' background as teacher or support person. On the other hand diversity and personalized learning path was pretty poor taken into account in the courses already finished.

Half of the respondents, especially persons with longer experience, have constructed web-courses on a certain approach. Majority of teachers and supporting personnel considers web-based learning supportive to the face-to-face teaching. Awareness of the chosen pedagogical approach of a web-course is not very high, as about half of the respondents planned the course according to a specific pedagogical approach. There is practically no difference here between teachers and supporting staff. Opinions as follows were given as descriptive to the issue of pedagogical approach: *"Open, problem oriented, contextual"*, *"Learning by doing. Rapidly in to the practice"*, *"Exploratory learning."*

As to the issue of collaboration in the courses realised by the team members, a clear statement shared by almost all respondents was that just little, at the best some, collaboration was gained. As descriptive for collaboration were given such statements as "discussions in the web" (4 mentions), "shared goals in a group" (3 mentions).

The role of the teacher in web-based learning is a generally known issue. In this study the question was formulated as follows: "Which role at the best would be your choice: teacher, tutor, expert, service provider?" The respondents tended to appreciate the role of a tutor / mentor. After the role of a tutor, secondly that of a teacher and thirdly an expert was given without any great difference in the background of the respondent.

The survey shows that emphasis in course production has moved from technical and practical matters to careful planning, considering the course as an entity, its' structure and interactive elements as well as visualization. The role of technology has become less important, although technical matters are still carefully considered in order to find the best technical solution to each course. The goal is to produce web-courses with readable, illustrative and interactive content, which is technically reliable and easy to access. Thus the most time-consuming phases in course production are producing and editing material into electronic form, suitable for the chosen learning environment. This includes planning and producing course contents, examples and animations.

Over half of the respondents (n=8) have nowadays a little more positive attitude towards web-learning than they had in the past. Considered that the team members do their job out of their one choice, also when appointed by the institution, and find their task meaningful, this is not a surprise. One fourth (n=3) have nowadays a lot more positive attitude towards e-learning than before. Three respondents stated that their attitude has not changed. Experience in web course production seems to have no effect on the change of attitudes. The somewhat reserved attitude towards virtual learning, experienced by many respondents has not discouraged the team members, anyway. The colleagues at the respondent's department have a positive and curious attitude on web-based learning, but also prejudices towards "new and unknown". Also students have a positive stand with some reserve.

One factor that affects the experience in the team is the expectations towards quality of web based learning. Over half of the respondents (n=8) estimated that the quality of web-courses is fairly good compared to traditional learning. Six respondents argued the quality to be good or very good. Careful planning and production reflects to the quality. There are several critical factors related to the quality of web-learning. According to the respondents the material should be readable and illustrative. Technical solutions are not the main issue in course production, but should be considered carefully to find reasonable and functional solutions for each course. Material should be easily accessed over distance and time. Technical and pedagogical support for teachers is of crucial importance. Guidance and support of students has to be organized. ICT-skills of students and teachers reflect to the progress of the course. Although web-courses attach value to teaching being available over distance and time, a timetable and some dates have to be given according to the respondents.

BEST COPY AVAILABLE

Conclusion and Discussion

The group of respondents seems to take a cautious start in virtual learning. They combine the elements of traditional face-to-face teaching with the modern technical facilities, with the will to keep on personal contact, tutoring and collaboration. In the practice, anyhow, personal contact and collaboration was poorly realised. Altogether in the EFVU project it handles a small scale production of learning materials, where members of the team are familiar with various tasks. The task is generally seen very meaningful. In the present stage of development this seems a rational arrangement, also if there is, of course the question, how much academic staff should be involved in www-page productions etc. (See Ryan et al 2001, 71-72) In this form e-learning is an additional element in teaching. No meaningful differences were detected in different areas of the study in comparison between respondents with teacher background or supporting staff. For the first group developing web courses is more rewarding than to the others, though. The members of the team with longer time experience are strongly directed by personal enthusiasm, whereas newcomers see their job more regulated by the institutional side. This is a signal of a more institutionalized dimension and growing acceptance. The team members show quite little awareness of the pedagogical approach in web course design. A constructivist approach in pedagogy could be acknowledged as a primary orientation in the team (compare with Salmon 2000, 35-36), on the other hand this is not specific at all. It seems, anyhow, that after the first 1,5 years of work this could be changing, and more attention will be paid to careful planning, also with didactic aspects in the production process. On the other hand the closeness of web course production to the teaching and teaching institutions is a garant for didactic consciousness, a matter that not so easily could be detected through the questionnaire.

As noticed above, much attention should be paid to the careful planning. This is also a point Ryan et al (2001, 77-78) recommend, with the help of concept maps and such, for team members to facilitate project management. Documenting the process would also be of great importance.

Some of the findings above could be reflected to the general trends in web-based learning. The will to take diversity into account is somewhat similarly reflected by the team members as for instance the study of Institute for higher education policy (Quality on the Line 2000) shows. Major institutions in e-learning in their specifications do emphasize student centredness but leave personalised learning aside. One has to acknowledge, though, that learner style adaptation is a debated area also when in many ways learners are different, starting from visual, auditory or kinesthetic learning preferences (see McVay Lynch 2002, 16-17).

The role of the teacher is in a lively stage. The group concerned in this study might not be so far that they would name the teacher e-moderator (see Salmon 2000), but they are eager to find new approaches in teaching. The point of view is pedagogical, in any case, not just technological one.

The quality of web-based courses done in the team was not evaluated by any systematic criteria. The comparison between the traditional teaching was more a numerous matter, of credits given. The idea of e-learning quality as a matter of system including elements of student and faculty support, infrastructure etc (see Quality on the line 2000) were not thoroughly considered. The focus of this study, anyhow, was more to find out the orientation of the team members, after 1,5 years of work, and in this function the findings are useful for the further development and becoming conscious of factors important in the process.

A Pervasive Computing Solution to Asset, Problem and Knowledge Management

Suman K. Kalia, Charles C. Tappert, Allen Stix, and Fred Grossman
School of Computer Science and Information Systems
Pace University, USA, ctappert@pace.edu

Abstract: A pervasive computing approach to asset, problem, and knowledge management reduced the average time to complete all major helpdesk tasks, and led to faster data availability, improved data quality, improved help desk effectiveness, improved help desk Return on Investment (ROI), lower overall Total Cost of Ownership (TCO), and increased user satisfaction. We describe the conceptualization, design, and construction of wireless laptop and PDA-based asset, problem and knowledge management systems. The systems work on a Lotus Notes/Domino-based server, supporting both wired desktops and wireless laptops and personal digital assistants (PDAs), to assist in the management of a divisional desktop support team across the U.S.

Introduction

The following quote (IBM Pervasive Computing Website 2002) indicates the importance of pervasive computing in managing information: "*Information is the new currency of the global economy. We increasingly rely on the electronic creation, storage, and transmittal of personal, financial, and other confidential information, and demand the highest security for all these transactions. We require complete access to time-sensitive data, regardless of physical location. We expect devices – personal digital assistants, mobile phones, office PCs and home entertainment systems – to access that information and work together in one seamless, integrated system. Pervasive computing can help us manage information quickly, efficiently, and effortlessly.*" Although the term "pervasive computing" is relatively new, its concept has historical precedence. Companies like IBM (IBM Redbook 1995) and United Parcel Service (Brewin 2002) implemented pervasive computing infrastructures as far back as 1982, and the IBM system was developed, as was our system, to improve the effectiveness of Field Technical Support personnel. Pervasive computing is all about access to your information, anytime, anywhere, from any device.

The system described here was developed for a company, hereafter referred to as ABC Company, that spends more than three billion dollars a year to procure technology. A major portion of this expense is for new desktops, servers, and associated peripherals. In spite of such a huge yearly investment, there has been no system to consolidate the technology procurement and to track the assets throughout their life cycle, making it difficult to compute the TCO of the assets. Also, there was no knowledge transfer of the kinds of problems encountered and the procedures followed by different support groups on such hardware/software throughout the organization. This is not only ABC Company's problem, but also one that is much broader and requires the attention of the industry

This paper summarizes a dissertation (Kalia 2002) that studied the effects of pervasive computing on the management of a technology Help Desk environment. The research activities included the conceptualization, design, and construction of wireless laptop and Pocket PC 2000 Operating System PDA based asset, problem and knowledge management systems to assist a divisional desktop support team across the U.S. The systems worked on a Lotus Notes/Domino-based server supporting both wired desktops and wireless laptops and PDAs. First, we created a baseline from our desktop computing Help Desk environment. Then, we established a pervasive computing implementation and measured the change in the quantity and quality of Help Desk calls handled. We hypothesized that the pervasive computing implementation would reduce the time to complete the helpdesk tasks, speed data availability, improve data quality, improve help desk effectiveness, improve help desk ROI, lower overall TCO, and increase user satisfaction.

Pervasive computing has its limitations, and one source (Grimm 2000) lists three scope-limiting areas: user interface and form factor limitations, network constraints, and multiplicity of administrative domains. We have removed, or at least lessened, the effect of these constraints by applying suitable limitations on the scope of our implementation. We addressed the user interface and form factor limitation by limiting the devices used to the Compaq iPaq PDA that uses the Pocket PC 2000 operating system, desktop and laptop computers running current versions of the Microsoft Windows operating system, standardizing the laptop selection on the IBM ThinkPad. We addressed the network constraints issue by limiting the network architecture to our corporate Intranet with its wired Ethernet and wireless 802.11b access, and no access was made available from outside this infrastructure. We addressed the multiplicity of administrative domains limitation by limiting a user logging on to the network from a desktop, laptop, or PDA to a single network identity (User ID and Password) for authentication.

Methodology

The project was divided into two phases: baseline and pervasive computing. For the baseline phase, January through December of 2001, we developed a suite of asset, problem and knowledge management applications in Lotus Notes and implemented them in a pure desktop-centric client/server environment. In the baseline phase, we captured the asset, problem and knowledge management data from the three sites: Tampa, FL, Boston, MA and New York, NY. In the pervasive computing phase, January through April of 2002, we used the handheld computers and collected similar data for comparison purposes. All data were replicated across the WAN at regular short intervals and made available across the country to 5,000 plus users through Lotus Notes.

Figure 1: Network Architecture

Figure 1 shows the overall network architecture used for this application in the three supported locations, the configuration of wired Ethernet LANs at each location, and the Wireless Access Points that allow wireless laptop computers and PDAs to be an integral part of this network. It also indicates the positioning of the Lotus Notes servers that house the applications and databases, and the data replication topology used to keep the databases at all locations in synchronization. The PDA clients consisted of two models of the Compaq's iPaq PDA using the Pocket PC 2000 operating system. The desktop and laptop client application development was all done using Lotus Notes development tools. Lotus Notes is a workflow development tool, which integrates, e-mail, text databases, workflow, and forms. The downloading and reformatting of Lotus Notes data to fit on the smaller PDA screen was done using Cadenza, a PDA based Lotus Notes client developed by Common Time, Ltd., that reshapes the data presentation to fit on the smaller presentation area of a PDA screen to integrate with Lotus Notes.

Asset, problem and knowledge management systems were designed, developed, and deployed in a client/server environment to provide a suite of Help Desktop applications supported by a set of corresponding back-end Lotus Notes databases. The Asset Management System was developed to provide an on-going tool to capture desktop hardware and software asset information. We used Lotus Notes because all users had Lotus Notes on their desktops

BEST COPY AVAILABLE

and Lotus Notes servers were already present to support these applications. The Problem Management system is a workflow application developed in Lotus Notes and used to record all incoming desktop problem calls. Each desktop has a Problem Management icon to invoke the application. The application enables a desktop user to enter his own problem calls; or optionally call one of the helpdesk agents and have them record the call on his behalf. Once recorded, a call may be viewed from New York, Boston, or Tampa instantaneously. A recorded problem is also automatically reported to the assigned engineer for immediate action. An engineer has multiple ways to find out about, and address, a reported problem. He may use a hyperlink in the e-mail message to jump directly to the problem record in the Problem Management system, call up the Problem Management application itself and select only his calls, and/or he may even review and accept other people's calls and address them. The Knowledge Management system feeds off of the Problem Management database and is merely a reporting mechanism. It allows a Field Service Engineer to immediately retrieve information on past problems by category (printer problems, LAN problems, etc.), and provides a basis to perform more extensive analyses of problems, solutions, and trends.

The client/server architecture supported the suite of applications. Clustered Compaq servers hosted the various Lotus Notes/Domino servers that supported the Notes based applications. The components consisted of Lotus Notes/Domino Web Server clusters, LAN/WAN/Wired/Wireless Network infrastructure, and Clients. We chose to use the Lotus Notes/Domino servers as our data repositories and Web servers for simple seamless data replication across our locations, for faster development, and for easy future enhancements. The standard Lotus Notes E-mail architecture across the company made it a convenient platform for the research and implementation. The network infrastructure was based on the existing infrastructure at ABC Company, augmented with new wireless capabilities. Data synchronization was necessary to present the same view of the data at all locations, and was a key objective of this project. The three Lotus Notes/Domino server clusters were located on the ABC Company Corporate backbone and thus shared the same wide area network across the country.

Results

During the baseline and pervasive phases, we collected approximately 12000 Lotus Notes records, each corresponding to a help desk call and containing the following information: the engineer responding to the call, the date and time the call was initiated, the date and time the call (task) was completed, and the support category of the call. We downloaded these records into a spreadsheet and removed those of calls not completed within the day received – that is, where the date of the call did not match the date of completion – because they may not accurately represent the time to completion that we were interested in analyzing. We discarded about 2400 records through this data cleansing process, leaving 9662 records suitable for our comparison testing. The records were sorted by date and divided into two groups to represent the baseline phase (Jan-Dec 2001) and the pervasive phase (Jan-Apr 2002).

We then sorted the calls by category and found that more than ninety percent of the total 9662 records belonged to fifteen dominant categories according to total sample size, and that these categories were reasonably represented in both the baseline and pervasive phases. The remaining 731 records not in the fifteen dominant categories were consolidated into a single "catch all" category. Most of the categories (all but 3 and 4) fall under Gartner's technical support category (Berg et al. 1998). The sixteen categories are: LAN connectivity problems, Lotus Notes install, printing problems, hardware – equipment procurement, new software installations, LAN password resets, in-house application support, software – problems, hardware – new installations, Internet support, Lotus Notes ID creation, new user set-ups, LAN account lockouts, relocations, mobile PC support, and the remaining categories combined.

Table 1 lists the sixteen categories by descending sample size – that is, the sum of the number of help desk calls in both the baseline and the pervasive phases – and, for each category, presents the total sample size, the baseline sample size, the baseline average time to completion, the pervasive sample size, the pervasive average time to completion, the decrease in the average time to completion in moving from the baseline phase to the pervasive phase, the percent decrease, the corresponding Chi Square statistical test value, and the corresponding null-hypothesis probability (p) value as a decimal and in scientific notation. The totals and overall statistical test values (for all 16 degrees of freedom) are also shown at the bottom of the table.

All categories benefited from a decrease in the average time to completion of the tasks, with the percentage decrease ranging from 3 to 62 percent. From the p values it is clear that the benefit of moving from the baseline to the pervasive implementation is statistically significant for most of the categories; eleven of the sixteen category decreases were significant with $p < 0.05$, and most of these, as well as the total, were significant with much lower p values. Therefore, the move to the pervasive implementation to handle help desk calls was highly beneficial. The engineers spent less time commuting, worked on more complex problems, and their productivity increased to handling three times as many calls per month.

Task	Total Sample size	Baseline Sample size	Baseline Avg Time (sec)	Pervasive Sample size	Pervasive Avg Time (sec)	Time Decrease (sec)	% Decrease	Chi-Square	p (decimal)	p (scientific)

Table 1: Average Completion Time of Baseline Versus Pervasive Phases for 16 Task Categories

Conclusions

We can now determine how closely our results match our hypotheses. From the statistical test results, there is no question that that the benefit of moving from the baseline to the pervasive implementation *reduces the time to complete the helpdesk tasks*. Compared to the first four months of the baseline period, the number of calls handled from the four months of the pervasive period tripled to *speed data availability and improve data quality*. A trend analysis showed that we could handle more calls because there is less commuting, a wider Knowledge Base, and remote access to all tools, *improving the effectiveness of the Help Desk*. The more effective Help Desk handled three times the number of calls with the same staff, clearly *improving ROI and TCO*. The increased number of calls is also a good indicator that the implementation of pervasive computing *improves user satisfaction*, which was verified by feedback from the engineers who worked during both the phases.

We provided an integrated suite of asset, problem and knowledge management applications and found that these three solutions, taken together, provided benefits greater than the sum of the benefits that these applications would have provided individually. With the TCO of a desktop computer estimated at $10,000, the non-purchase factors far outweigh the cost of purchase (Berg et al. 1998). The only way to reflect these costs accurately is to keep asset and problem management data together so that we can see how the cost of ownership increases as the hardware and software age.

As a further benefit of centralizing these data, we were able to evaluate the effectiveness of our Field Service Engineers. These data also provided a free source of training for them, since they could see the types of problems that they were likely to encounter in practice and the solutions to those problems, and this free training resulted in significant savings in training expense and enabled the company to utilize engineers with a lower skill set.

Web*KANE*cts

Building on constructivism
to create
a learning-centred strategy
for e-learning.

Catherine Kane
Centre for Learning Technology / Information Sysytem Services
Trinity College Dublin
Ireland
Catherine.Kane@tcd.ie

Abstract: This research explores the development of a new strategy for e-learning. A strategy based on aspects of constructivism, that allows the learners to build their own learning environment based on new learning material, prior knowledge and experience. I call this new strategy **Web*KANE*cts**.

The methodology of Web*KANE*cts pulls together many existing ideas and strategies into a new focus for education. It is closely linked to the WebQuest strategy (Dodge, 2000). Resources to support the learning are designed as Learning Objects (Bannan-Ritland et al, 2000) and the environment is delivered using an Expert System, **Exesys Corvid** (http://www.exsys.com/1.2NR.html). My strategy takes what is best from other systems and makes the 'Web*KANE*ctions' necessary to empower the learner and the teacher.

An artefact has been developed for and tested by second year Botany students at Trinity College Dublin, Ireland. The strategy has also been examined by three experts working in the field of IT in Education.

Introduction

If we are to embrace the challenge Information Computer Technologies (ICT) in education presents us with, then I believe we need to examine new methods of learning and teaching. We need strategies that embrace these new technologies while still taking into consideration established theories on education and learning. I want to develop and test a strategy that enables the learner to compile his/her own learning objectives, where content, context and assistance support the learner and help him/her make sense of the ever more complex world we live in. This strategy should also encourage the learner to draw from his/her own experience and knowledge to create new knowledge. It should go above and beyond the use of educational theories used in traditional text-based learning environments.

Needs survey

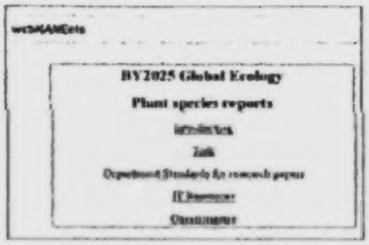
In the course of my profession as a Trainer in the Department of Information Systems Services, Trinity College Dublin, and from working with new entrant student annually, it has become apparent that many students enter College with little or no IT skills. Earlier research in this area (Kane 2001) had highlighted this problem. I hoped to build on this research while developing a new strategy for e-learning.

A needs survey of 200 second year Biology students showed the following results. 35.7 % of the students reported having no previous experience with e-mail, 27.1% reported having no Internet experience, and 22.1% reported no experience with Word Processing.

Based on this information I decided to develop an artefact that would support these students in the use of College computers to complete assignments.

Structuring the Learning Environment

I structured the artefact in the same format as a WebQuest.



BY2025 Global Ecology

Plant species reports

Figure 1 - Screen shot of system showing all sections.

The Resources section consists of IT resources that may be helpful in completing the task. These resources have been developed as individual learning modules. The student is asked to pick the modules he/she thinks will help them to complete the task. This is where the students build their own learning environment. If the student knows how to perform a task then he/she can choose not to select that module. Subject related resources could also be made available. For our test all resources were IT based.

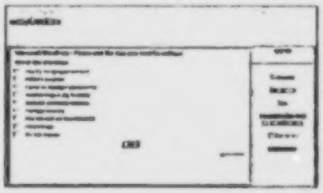


Figure 2 - Shows a list of Microsoft Word Help choices available to the student

Note: "Filestorage" in Trinity College is a protected central storage area independent of the networked computer from which files are saved. Each user is allocated 30 MB of private "Filestorage" space.

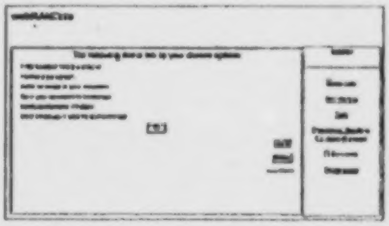

Figure 3 - A student's personal learning environment.

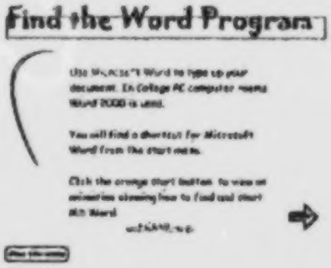
Each learning object deals with one small chunk of information. Text and animations are used to teach the procedure.



Find the Word Program

Use Microsoft Word to type up your document. In College PC computer rooms Word 2000 is used.

You will find a shortcut for Microsoft Word from the start menu.

Click the orange start button to view an animation showing how to find and start MS Word

Figure 4 shows a screen shot for the help item **Find the Word Program**.

Findings

Students were asked to fill in a questionnaire to establish how helpful they found the system

Taking a look at the number of times *not helpful*, *helpful* and *very helpful* had been selected across the full survey. There were a total of 161 responses. 90.7% of these responses had found the learning modules either *helpful* or *very helpful.*

Category label	Code	Count	Pct of Responses	Pct of Cases
Not Helpful	1	15	9.3	75.0
Helpful	2	94	58.4	470.0
Very Helpful	1	52	32.3	260.0
	Total responses	161	100	805

10 missing cases; 20 valid cases

In a second phase of testing three experts in the field of IT in Education were asked to examine the strategy. I asked them to use the system and at the same time talk about their experiences, feelings and emotions. This type of research is referred to as verbal think aloud analysis (van Someren M.W. et al, 1994).

The three experts were Dr Bryn Holmes, Ms Valerie Carroll and Ms Catherine Bruen. Dr Bryn Holmes is the course director of the M.Sc. in IT in Education at Trinity College Dublin and has a PhD in Information Technology in Education from the University of Cambridge. Ms. Valerie Carroll and Ms. Catherine Bruen are Educational Technologists at the Centre for Learning Technology, Trinity College Dublin.

All three experts had very positive things to report on the strategy. They highlighted the overall look and feel of the project as been very professional.

Holmes and Bruen both referred to the system as being like your friend or buddy.

> *This would be my buddy. Once I'd learn these 9 or 10 things I'd use them again and again for other assignments.*
>
> (Bruen 2002)

Both felt the students might turn to this system rather than asking a friend. Holmes suggested that this system might not be used as I had first envisaged but that students might be inclined to return to it later for short pieces of help when needed.

Holmes felt a system such as this that laid down what the task was, what standards should be followed and what needed to be done was comforting. She felt a strength of the system was how it was suited to both expert and novice users.

> *Although certain courses might be well suited to beginners and others to experts they tend not to be the same course, but this structure offers this advantage.*
>
> (Holmes 2002)

Holmes felt both novice and expert could use the system in the same room at the same time and while working on the same task. She added that while most people come to a subject with some experience a structure such as this allows them to build on that previous experience and motivates the learner to expand their knowledge.

Bruen said she would find comfort in having a system she could visit and revisit as needed. She liked the fact that the resources were limited to what was needed in order to complete the task and reported having difficulties at times with help systems built into programs.

> *...help never works. I can never find what I am looking for. This on the other hand is tailor made to support the task.*
>
> (Bruen 2002)

On a more negative note all experts reported finding the navigation slightly confusing. The students had been given a run through the system before they had to use it. Carroll suggested that the system relied too heavily on the students having attended this orientation session and that not enough help was built into the system. She suggested prompting the students with some questions such as:

> *Do you need to brush up on your computer skills? Then check out IT Resources.*
>
> (Carroll 2002)

BEST COPY AVAILABLE

As someone who has worked extensively with the WebQuest strategy she felt elements of the WebQuest strategy had not been utilised enough to guide the student, in particular the Process section.

Carroll also suggested that examples or sample reports that showed what was expected would be helpful. She suggested using the Evaluation Section for this purpose. She would also have liked some way to integrate this program into the task so the students could try things for themselves without leaving the environment.

> *I would like to be able to try this for myself. There should be some way to integrate this into the task.*
>
> (Carroll 2002)

Further Research

I believe that as technology becomes more available to our students and our institutions we have no option but to embrace this new tool and look for new ways to integrate it into our teaching and learning. Firstly our students must know how to use the technology and secondly the technology itself must be seen as a tool for teaching and learning in other disciplines. I am interested in embedding the transfer of IT skills through subject related topics. I believe my new strategy is one possible way of advancing this aim. I based this strategy on sound educational theories of constructivism and closely examined current trends, but I believe I have also pushed out the boundaries in search of something new.

The Department of Information Systems Services are supporting a team, lead by myself to develop a set of resources on using College Computing Facilities that will follow my strategy of delivery and design. These resources will support an already established induction course run by the department for new entrant students each year.

Once developed these resources will also be available to the Centre for Learning Technology for inclusion in projects that support the use of ICT in Education. Projects similar to the Botany project (the pilot for this study) will benefit. All resources will be developed as short modules dealing with specific tasks that can be compiled in different combinations for different contexts and to achieve different learning outcomes. Standards in design and implementation will be set to make the reuse of resources possible.

In order to establish whether or not this strategy is successful, I believe it is necessary to build many more learning objects and to test their use and reuse over several tasks and assignments. Records on how students are using the modules, whether they are building on previously used modules to solve new tasks or revisiting old modules, and establishing what connection they are making between old and new resources, will be necessary. This type of ongoing research will take time and cooperation from a target group of students.

I believe there is also a need to build a specific tool to support the construction of these learning environments. This tool might allow the student or the academic to build their own environments, allowing them to add resources that could be shared and used alongside built-in resources. Such a tool would need to be easy to use both for the Academic and the learner and I believe, should not be tied to any one content type or subject.

An Analysis of the Capabilities of a Self-study Support System for Network Education

Satoshi KASHIHARA, Shinichi FUJITA, ChunChen, LIN, Ming YIN Seinosuke NARITA
Waseda University
3-4-1, Okubo, Shinjuku-ku Tokyo, Japan
601c0319@mn.waseda.ac.jp

Abstract: A great number of pieces of research are being conducted on introducing computers into conventional face-to-face education to make it more effective. The present writers also have successfully developed a system for language lessons conducted at school as well as for reviewing the lessons. This system has the capability of providing learners with videotaped contents of language lessons, so that they can use them for their self-study. This system, however, has recently been confronted with a problem, which was raised by the learners, of being unable to provide them with excerpted information that they need. Although learners are required to spend more time on reviews than lessons or preparations in order to acquire a foreign language, no effective system for reviews has been proposed yet in reality. This thesis describes the present situation in which school education networks are being used, and also makes an analysis of the capabilities of the aforementioned network-based effective system for self-study, taking the state into consideration.

1. Introduction

Education, including e-learnig, may be classified into two types according to whether or not it is carried out under time constraints; education that is carried out under time constraints is categorized as synchronous education, and education that is carried out otherwise is categorized as asynchronous education. Synchronous-type education refers to education that requires every learner to simultaneously take part in lessons. There are two subcategories of education of this type; interactive synchronous systems, which include SCS (Space Collaboration System) (see [4] below), and pseudo-interactive synchronous systems, which include Waseda Learning Square (see [5] below). SCS is well-known as an interactive synchronous system that networks higher education institutions throughout Japan, including national, public, and private colleges, universities, and technical colleges, by the use of a communications satellite. Asynchronous-type education refers to education that allows learners to study whenever they like under no constraints of time, and includes paper-based correspondence education that used to be popular before the Internet gained popularity as well as WBT (Web-based training).

In the area of educational engineering, research is currently being conducted on asynchronous-type lessons, and there are some groups that are making practical use of this type of education. Education of this type, which allows learners to study at their own pace, is considered to be suitable for self-study for reviewing lessons, self-study that aims to acquire and fix knowledge, and drills that learners are required to do repeatedly. The writers have repeatedly mentioned this type of education has the advantage that it can be carried out under no constraints of time. At the same time, however, the writers cannot avoid pointing out the disadvantages of this type of education. In the concrete, there is apprehension that it may not make learners feel they are participating in lessons for the following reasons; teachers cannot easily grasp the situation with regard to each learner's understanding and learning, and learners cannot easily grasp the situation of other learners, either. Accordingly, this type of education may not key learners up to concentrate their attention on lessons. There is also apprehension that this type of education, which may not allow learners to know the situation of others, cannot easily raise motivation. Although there are some defects in the synchronous-type network education, it is still widely used .

Although the aforementioned synchronous-type network education is widely implemented, emphasis is laid, for the time being, only upon giving lessons through networks without any consideration of its functions. Particularly, there are few systems with a well-examined self-study system that can closely relate lessons to preparations and reviews that learners have to do. The following take the case of the self-study support system that was developed and has been practically used by the writers, namely, EDLIN, in order to discuss how to relate school-based lessons to self-study that has to be done by each learner.

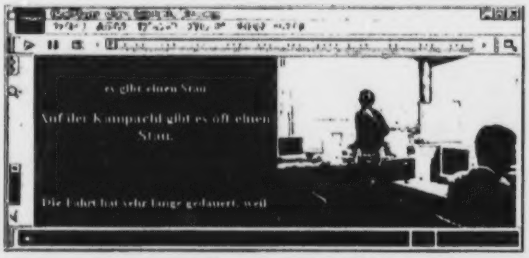
2. The Issue of EDLIN's Self-study Support System

The study group that the writers join developed a LAN-based integrated education support system named "EDLIN" (Educational system Developed for Learning on the Internet and an intraNet), and then has used it practically on the scenes of lessons.

According to the aforementioned classification, lessons conducted with EDLIN are categorized as synchronous-type education. EDLIN is intended for a lesson conducted at a computer room where a teacher and student are each provided with a computer on a LAN to communicate with each other, and aims not only to support the lesson being conducted at school but also to comprehensively help the students do their preparations for lessons as well as review lessons. In order to support the lesson being conducted at school, EDLIN includes various capabilities as follows. First, EDLIN includes the capability of serving as an electronic blackboard, which allows a teacher to input what should be written on a blackboard with a keyboard and then to distribute it to the students via an electronic medium, or the aforementioned network. Second, EDLIN includes the capability of transmitting data files, which allows a teacher to transmit data files necessary for his/her lesson. In addition, EDLIN includes the capability of allowing students to use electronic notebooks through keyboard entry, so that they can take notes of a lesson as they like, and that they can refer to them to review the lesson afterwards.

The following describe the aforementioned self-study system in a little detail. The study group the writers join constructed a self-study system, which aims to help learners do their preparations for lessons and review lessons at home, on a typical information providing system of the Internet, namely, the Web. Any student who has access to the Internet at home can use this Web-based system to do his/her preparations for a lesson as well as to review a lesson whenever he/she likes. This system also has the advantage that it enables those who have developed and used it to keep providing students with the latest version of the system by promptly updating a Web server with modifications made to the system. This is the outline of what the system realized by the writers is like and how students can use the system to do their preparations for lessons and review lessons at home. When the aforementioned system was practically used for preparations for lessons, students could study in advance what was going to be dealt with during the lessons at home or somewhere else by the use of its database system for words and grammar and its system for drills and exercises, both of which were made available to them on the Web by the aforementioned study group.

The system uses streaming distribution technology to provide, on the Web, students with not only videos of the lessons that were actually conducted but also data that was input on an electronic blackboard by a teacher, so that the students can review lessons with them. When the system was practically used, students could review lessons by getting access to the streaming data distributed on the Web. EDLIN includes the capability of synchronizing the images of ideotaped lessons and the text data prepared on an electronic blackboard with a teacher's application as well as the capability of automatically uploading the synchronized data to a Web server. These capabilities make it possible to create Web contents available for review almost automatically, and therefore save the teachers who use this system time and labor. This is an original feature of EDLIN.



es gibt einen Stau

Auf der Kampachi gibt es oft einen Stau.

Die Fahrt hat sehr lange gedauert, weil

Figure 1 window for review in EDLIN

Figure 1 shows a screen that displays the contents distributed by EDLIN. It is a real screen that was used for review. An electronic blackboard and an image of a videotaped lesson, both of which are synchronized, are displayed in the left and right sections of the screen, respectively.

EDLIN, which enables students to review the contents of lessons conducted at educational institutions such as schools by getting access to the Internet, was considered to be a very effective self-study support system. However, there occurred an issue concerning this self-study support system when students reviewed lessons with their electronic notebooks. The point at issue was that the students could not excerpt the part that they needed to watch again. In other words, the students had to watch the whole videotaped lessons from beginning to end in order merely to review the part they could not understand. In reality, the students must have wanted to excerpt the part that they regarded as questionable or the part that was regarded as related to the aforementioned part when they actually reviewed lessons with their notebooks. Taking this into consideration, the writers must admit that this system, which

BEST COPY AVAILABLE

compels the students to watch the whole videotaped lessons when they review, is extraordinarily inefficient. The writers are now determined to construct a better self-study system by drawing upon the analysis that has been made up to the previous paragraph. In the concrete, the writers intend to construct an education system that would be available to lessons as well as self-study through a network. This education system enables students to excerpt the images and sound of the part that is related to what they cannot understand when they review lessons while referring to the notes they took with their electronic notebooks during the lessons. This feature would help the students review lessons efficiently.

3. How a Self-study System for School Education should Function

The writers would hereafter discuss how a self-study system for school education should function, taking into consideration the results of the analysis of the capabilities of EDLIN's self-study system. The flow of a study system for school education can be divided into the following three steps; the first step that corresponds to a preview, the second step that corresponds to a lesson conducted at school, and the third step that corresponds to a review. In learning, each step is so important that any of them must not be skipped. Moreover, each step determines how learners relate to their teachers, how the system helps learners and teachers, and what role should be played by learners, teachers, and the system, respectively. When the self-study system being herein discussed is used in a lesson, it shall help one teacher and a number of students have bidirectional communication smoothly, so that a lesson can be conducted more efficiently. When the system is used for students to make preparations for lessons, it shall help them use their notebooks and skim through their textbooks, so that they can grasp the gist of what is going to be dealt with in the following lessons as firmly as possible. When the system is used for students to review lessons, it shall help them deliberate on what they have taught by their teachers and try to understand on their own. If there is anything ununderstandable to the students, they may wish to listen again to what their teachers have explained in order to get a grasp of it. In this case, the students may not wish to listen to the entire lessons but wish to focusing on what they cannot understand.

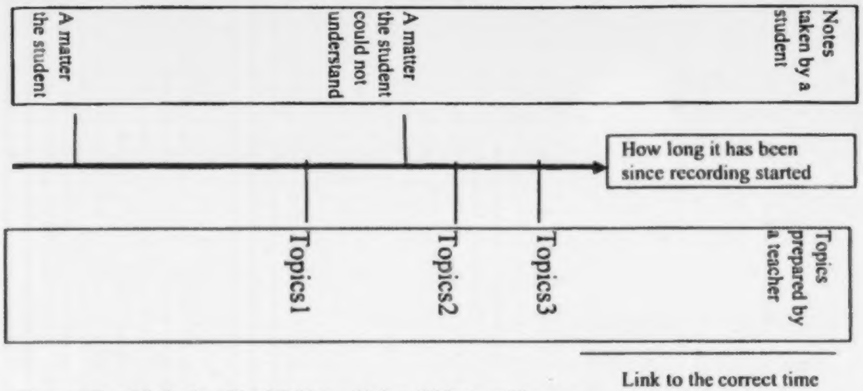
Up to now, EDLIN has helped students review lessons on their own by distributing the entire part of videotaped lessons on the Web. This method is very helpful to students who missed lessons and those who cannot understand the contents of the lessons at all and therefore wish to take lessons from beginning to end again. However, this method is not so helpful to students who need to review only several parts that they could not understand during the lessons. As stated before, such students do not need to listen to the entire part of what their teachers explained during the lessons but desire to listen to the excerpted part that they need to review. In order to "excerpt the required part", each videotaped lesson shall be given indexes of the following two types:

1. a time index that can be linked to each time point a student took a note with his/her electronic notebook during a lesson
2. a keyword index based upon the topics prepared by a teacher; this type of index can link each part of the contents of a lesson

Each student can use the former type of index simply by making his/her electronic notebook memorize the time he/she takes a note of a matter explained by his/her teacher. The electronic notebook is designed to record the time a note is taken in such a manner that the aforementioned time corresponds to the time period from the beginning of a lesson to the time point a note is taken. Accordingly, the student can pinpoint when the matter he/she took a note of was explained during a lesson. The electronic notebook has the capability of searching the notes that were taken with it. With this capability, the student can search for the matter that he/she needs to review, pinpoint when it was explained by his/her teacher with the index, and then directly access the applicable part of the videotaped lesson for reference.

The latter type of index is based upon the topics that would suggest what is being explained by a teacher. The teacher prepares these topics, and then marks the applicable part of the videotaped lesson with them, so that each topic can be timely linked to the applicable part of the videotaped lesson.

As stated up to now, it is required to construct a system that would enable each student to efficiently review the part that he/she could not understand during the lesson with his/her electronic notebook or by searching videotaped images for the applicable topic prepared by a teacher. See Figure 2 for reference.



Notes taken by a student
A matter the student could not understand
A matter the student

Topics prepared by a teacher
Topics3
Topics2
Topics1
Link to the correct time

Figure 2 Two Methods of Establishing a Link to Videotaped Images

The following exemplify how the revised version of the present EDLIN is expected to function. The revised EDLIN may provide students with a system that would record each time a note is saved. Every time a student saves a note that he/she took on a matter explained in a lesson with the aforementioned system, the system would record the time, with which the student can establish a link to the applicable part of the lesson contents. The system is also expected not only to establish a link between the text data prepared by a teacher, such as the aforementioned topics, and lesson contents but to have the capability of searching the aforementioned text data. If these expectations are realized, it will become possible for each student to access the lesson contents that he/she really needs through the aforementioned link. As stated before, it is required to construct a system that would enable each student to efficiently review the part that he/she could not understand during the lesson by the use of his/her electronic notebook or by searching videotaped images for the applicable topic prepared by a teacher.

4. Conclusion

In this thesis, the writers have made an analysis of the capabilities of EDLIN, which they developed and have used, in order not only to discuss the importance of self-study as part of school education but also to examine the capabilities of the system that would usefully support self-study. Self-study is a stage of learning that cannot be skipped. It is no exaggeration to say that how efficiently a student can do his/her self-study may determine to what degree the student can understand the contents of a lesson. For the time being, most pieces of research being conducted are focused on how to use networks in order to conduct conventional-type face-to-face lessons at classrooms. Therefore, the writers must admit that there are few systems that relate the contents of lessons to self-study, and also that there are few systems that are constructed on the basis of a learning model of learners. Research on how to introduce computers and networks into conventional face-to-face education may be in the primary stage of the research on e-learning, and research of this kind has already become matured. It is high time for researchers to aim at developing a system that would help learners study with efficiency not only at classrooms but also at home. At the end of this thesis, the writers would conclude the system proposed hereinabove, which may allow learners to make the most of the contents of lessons to study by themselves, not only to keep up with the time but also to be very useful and considerate to learners.

JUST IN TIME LEARNING FOR SCHOOL SUPERINTENDENTS

Although the role of the superintendent is commonly cited as a keystone in school improvement, it is not the traditional role of times past. This presentation puts forth a more encompassing and collaborative perspective on leadership, suggested by Peter Senge (1999), that it is the ability of a group (not an individual) to sustain the purpose it has begun. This session presents the World Wide Web as a conduit through which superintendents can deliver mo re timely, more extensive, and more contextually appropriate resources to their administrative teams and teaching staffs.

The superintendent is not only the organization's chief executive officer for the learning experiences of children and youth, but the motivating agent and facilitator of adult learning for the administrative team, teaching staff, and community. These multi-dimensional tasks demand attention to the informating role that superintendents play for their varied constituencies. Informating, a term coined by Shoshana Zuboff (1988), is a useful concept for professionals who play such connective roles in the learning success of others. In contrast to the automating technologies that make our work more efficient, informating efforts stretch people to think differently about the work they do and then to use technology in improving that work. How then can the educational CEO keep his or her team connected with each other, and with resources that support the district's mission and that reflect "world class" standards?

The presentation uses a conceptual framework based on Rosabeth Moss Kanter's findings about "world class" organizations. Kanter points to three primary factors accounting for this level of successful group effort. They are: 1) improved thinking and problem-solving, 2) improved performance reflected by results, and 3) improved networking of individuals within the organization. She claims that world class organizations whether they are corporate, medical, or educational all support such an amalgamation of thinkers, makers and traders.

This presentation takes these three categories as organizing units from which to explore available electronic resources through which superintendents can connect the administrative and teaching staffs with information to stretch their thinking, improve their performance, and expand their connections to gurus in their field and to each other.

Integrating the web into a superintendents assistive approach to the learning of others exemplifies to a community a "marketing" as opposed to "sales" approach (Schlechty, 1997) to education. The traditional mindset for most organizations is looking at what exists in our warehouses and designing our offerings to reflect an existing product. Like many products, the shelf life of information in education too exceeds its limits. A major dilemma for veteran educators today is that those practices which accounted for their own professional success and the success of their former students grow increasingly obsolete. In both its informative and communicative capacities, the Web enables superintendents to foster a marketing approach linked to best practices and attention to the development of thinkers, makers, and traders, in any organization.

It creates a leadership arena less shaped by policy and bureaucracy and more connected with others on whose success the ability to sustain positive initiatives depends.

The Cost-Effectiveness of an Online Electric Circuits Course

Abstract: This paper describes an e-project in a college-level introductory electric circuits course. Online materials were developed using the Mallard® course management system. The project is acquiring empirical and other data on two critical issues: 1) Whether the course with its substantial online asynchronous components is as effective as a primarily synchronous course; and 2) The comparative costs of the new mode of online instruction, which replaces pen and paper exercises mediated by graders with self-help online instructional exercises and asynchronous online discussion. The project is comparing the modified online version of the course with a traditional version, and the overall design of the project can be considered a pre-test/post-test, control group design with a follow-up qualitative study. The paper then presents initial results of the project.

Introduction

A semester long university-level course on Introductory Electric Circuits establishes a foundation for the understanding that is required in circuit design and includes: an introduction to primitive circuit elements and basic circuit types derived from them; the application of key physical laws (e.g., Ohm's, Kirchhoff's laws) to circuit analysis; and the application of calculus and differential equation skills in analysis of circuit design. There was the recognition that this traditional synchronous course was to some degree "broken." To fix it, the heart of the course needed to be addressed – the paper and pencil homework problems, which are directly or indirectly related to 80% of the course grade and clearly related to student retention and overall success. As a result, an e-component was developed to address this issue.

The Course Management System

The principal software used in the project- is Mallard®, a course management system (CMS). Mallard® and other central CMS software at the university, such as Blackboard®, reside on a robust server serving some 30,000 users. Mallard® is web-based, allowing easy deployment into residential and non-residential environments. As a CMS, Mallard® is similar to others packages, but is especially useful for various types of math problems because it has the mathematical and computational functionality to evaluate and grade most types of problems in this course

The online course materials, the homework, is written in the extended HTML of Mallard®, are intended to replace the cumbersome and unsatisfactory process of solitary exchanges of paper problems with course graders. Online materials have been created that engage students, prepare them for future courses in circuit design, and provide for the potential of improved retention. While the broad content of the online course materials is adapted from a paper text source, the new materials are pedagogically and methodologically unique. For example, the complex equations and other aspects of the problem solutions submitted online by students are evaluated instantly. Further, the online problems are carefully deconstructed versions of the paper originals, which allow students to work to mastery through each element of the problem and at each point are provided detailed and immediate feedback on their mistakes. Students experiment and discover answers themselves and, when needed, have access to email where they can immediately query other students and the instructor for help. Some of the specific features of the online course materials include the following; Capability to program random values into problems so individual students get different numerical values in their problem statements; Immediate evaluation and grading of students' submitted problem solutions and return; Mallard® graded problem scores are automatically recorded; If solution is incorrect, student can rethink the method and submit another solution (10 times without penalty before the due date); Student can then pinpoint more easily where an error lies, and submit a corrected answer; Other student grades, such as exam scores, paper-and-pencil homework scores, laboratory scores, can be uploaded.

Project Description

A project, using the revised e-version of the Introduction to Electric Circuits course, was secured through funding by the Andrew W. Mellon Foundation Cost-Effective Uses of Technology in Teaching (CEUTT) Initiative that focuses on the cost and effectiveness of technology in higher education and whose goal is to identify and disseminate good practices, regarding methods of instruction, and measures of cost-effectiveness. The project is now acquiring empirical and other data on two issues: 1) Whether the course with its substantial online asynchronous components is as effective as a primarily synchronous course with similar material but delivered entirely by a standard lecture, recitation, homework, exam format; and 2) The comparative costs of the new mode of online instruction, which replaces pen and paper exercises mediated by graders with self-help online instructional exercises and asynchronous discussion mediated by the instructor and the students themselves. The plan is to compare the modified online course with a traditional course on the same material, and to measure cost and learning outcomes. The intent is to conduct this comparison working with current and upcoming enrollees in the course (three semesters of data).

The overall design of the project can be considered a pre-test/post-test, control group design with a follow-up qualitative study. In addition, the approach utilizes an entry-level assessment, non-intrusive data gathering throughout the project, post-course assessment, and a follow-retention test. Students in the course are divided into two groups, randomly assigned: (1) Group A and (2) Group B. During the first half of the semester Group A receives training and access to Mallard®, and is known as the ' Mallard group'; Group B is the traditional 'paper' group. In the second half of the semester, Group A no longer has access to Mallard® and switches to be the 'paper' group; Group B then receives training and access to Mallard®, and is the Mallard group. All students receive the same examinations, including the Final. Procedures are established to minimize any leakage across the groups, such as by controlling students' access to Mallard® for only certain parts of the semester. In addition to these two groups, a paper-only group and a Mallard-only group were established to satisfy requests from students who did not wish to partake of the regular 'experiment.' Although the number of students involved in these additional groups is small, the data do provide additional data analysis opportunities.

Data gathering consists of the following. (1) A pre-course instrument intended to measure the students' existing knowledge; a pre-course survey of attitudes; a pre-test instrument intended to measure the students' knowledge of content prior to receiving the course content; a post-test instrument intended to measure the students' knowledge and skill mastery after the course; a post-course attitudinal survey; and a retention test administered at a scheduled time during the semester after the course. (2) Grades on homework and exam; and numbers of time online homework submitted; number of interactions with teaching assistant; amount of time logged-in; etc. (3) But in addition, other approaches may be employed further along in the project, including the use of performance data, such as grades from course prerequisites, unstructured and structured interviews, observations of learners and instructors, examination of student work, and the administration of other instruments. The summative evaluation will consist of the aggregation of data gathered from the three offerings of the course but also emphasizes evaluation in terms of attaining the objectives of the project and of a more detailed analysis of student learning and outcomes.

Initial Effectiveness Results

Results in the Fall 2001 semester from both groups indicate a majority of students were 20-21 years of age (with a range of 19-38); were mostly male; and with English the primary language but with 7 other languages represented. The groups differed in terms of their majors; and a large majority of students were not freshmen or sophomores, although the course is recommended at this level. For the most part, prerequisite coursework was taken or being taken. The majority of students indicated no experience in analyzing or designing electronic circuits. There was variability between groups in terms of the amount of prior experience. A majority had some or a lot of interest in the topics of the course. For the most part students were positive in their self-assessment of the course-related content questions. Data were collected for Spring 2002 and compared to the earlier group. The Fall 2001 groups were slightly younger in age than the Spring 2002 groups, and, although English was the primary language of the majority of students, the Fall 2001 groups exhibited more language variability. Fall 2001 represented electrical engineering and biomedical engineering, and other majors, while Spring-enrollees were mostly electrical engineering majors. Although Fall 2001 students represented a variety of academic levels most Spring 2002 students were second-semester sophomores. A large percentage of Fall 2001 enrollees had not take CSCI 101L, the majority of Spring 2002 students had taken this course. Fall 2001 students exhibited variability in amounts of experience, while the majority of student in Spring 2002 groups had no experience.

Quantitative results for the Fall 2001 semester indicate that Group A and Group B performed differently on the various mid-term exams, but Group B seemed to perform better that Group A irrespective of their use of Mallard® or paper. The combined Mallard® and 'Mallard only' groups performed better overall on Midterms. The Paper Only Group did not perform well on exams when compared to Groups A, B, or 'Mallard Only.' For the most part, the homework grades of the Mallard group were higher. At this point in time, the means are not significantly different between the groups on the homework. For Spring 2002, there were no differences in the test performance of the groups on the same examinations; there was little difference between groups on homework performance.

Various qualitative and other results indicated that interest in the course was intensified. Student felt that it was "them against computer" instead of against the instructor. Some students couldn't sleep until they got the correct answer. The instructor of the course received more e-mail, office visits, and phone calls about homework than ever before. There were much higher homework grades, many were100%. Students liked the immediate grading and appreciated that they didn't have to wait a week for graded results. If a submitted solution is wrong, students liked being able to resubmit a solution up to 10 times without penalty before the due date. They felt that they learned from their mistakes while reworking problems. The majority of the students think that Mallard® should be continued in the electric circuits course.

Initial Cost Results

This project also has a cost focus. The approach to measuring costs in a project of this nature is to use Levin and McEwan's (2001) ingredients approach. This is accomplished by specifying the "ingredients" of each option considered, and by estimating the costs of each ingredient. Costs measurement is more than simply the expenditures (accounting systems typically report resource flows by object) involved in providing each ingredient, but also includes the concept of economic or opportunity costs (measures of what must be foregone to realize some benefit). For this study, expenditures and costs are being gathered for personnel, and for all other resources. In measuring the cost of personnel, much of the analysis focuses on opportunity costs.

One of the primary costs of development of the Mallard® system was the time of the instructor with an average of 159 hours spent per semester. As anticipated, over time the number of hours spent in development activities has declined. However, it should be noted that much of the development time for the fall 2001 and spring 2002 semesters was due to the study itself. In engineering courses using only the paper and pencil method, students traditionally are given homework solutions after turning in their assignments so they can determine if their methods and resulting solutions are correct or not. On the other hand, in courses using only Mallard® homework, solutions are generally not distributed to students because Mallard® automatically informs them of the correctness of their submitted answers. Assigned Mallard® problems can be used again in subsequent semesters since their solutions are not available from previous semesters. It was decided at the beginning of the study, to furnish homework solutions via the class Web site to both groups, i.e., everyone in the class. -As a result, solutions to all of the Mallard® problems assigned during the semester-are available to everyone in the class and in future classes, requiring the coding of many new problems. The instructor indicated that if all students in the class were using Mallard®, there would be virtually no costs for the development and coding of new problems. An additional development cost is that of teaching assistant time to learn Mallard and to code problems into Mallard. A total of 518 hours of teaching assistant time was spent in development activities. Individual rates of pay ranged from $7 per hour to $16 per hour. None of the teaching assistants appear to have received tuition remission in addition to their hourly pay for these activities. Note that *no* teaching assistant costs for development were incurred in the actual last two semesters (Fall 2001 and Spring 2002

Regarding instructional costs, allocation of instructor's time during the Fall 2001 and Spring 2002 semesters included preparation of lectures and exams, and coding of problems. As discussed previously four groups existed, thus other costs also includes creating and maintaining three Web sites and a paper-only database as well as shifting students from one format to another during the semester. It was therefore necessary to keep track of and administer four groups instead of two. This cost will be eliminated with the move to a Mallard® only format.

It is in the analysis of teaching assistant time that the most substantial differences in the cost of Mallard® and paper homework become apparent. There was no grading of Mallard® homework but, for example, in the spring 2002 semester, one teaching assistant whose time sheet shows a total of 125 hours in grading for the paper homework grading. If paper homework assignments were eliminated in favor of Mallard®, then most of the grading time would no longer be needed (teaching assistants would still have to grade the tests). Thus, the savings in time – and hence costs.

Data on student time on class activities are also available. Our hope was to compare the time students in the Mallard group spent on class activities to the time other students spent. But, student participation in this data collection activity was limited during one of the semesters, and we are continuing to ascertain the quality of the data by attempting to determine how consistent students were in turning in or not turning in the data collection sheets, and in allocating their time correctly to learning activities.

Maintenance and support costs are also being gathered, such as the Mallard® licensing fees (currently $1,000 per year), installation and maintenance costs, and user support costs (for faculty, teaching assistants, and for students). Unfortunately it may not be possible to get detailed breakdowns of the time spent by computer personnel in supporting Mallard and in providing user support. But it appears that as it relates to the entire university computer operation, the costs are relatively small. In particular, Mallard® is today a stable product that is not upgraded regularly, and is not widely used across campus.

Concluding Comments

The project is gathering data from at least one more iteration of the course (fall 2002); and is securing advice from a project Advisory Board that is reviewing the planning and design efforts, and the results.

Blended Learning at a Leading Executive Education Institute: State of the Practice

Abstract: A review over five years has shown the emergence of blended programs – combining face-to-face and ICT at a distance – at one of the world's leading executive education institutes. A review of current practice shows a wide variety of ICT employed in programs. We take a deeper look at how and why ICT is used, through a broad analysis of ICT use in programs, complemented by a case study of a design for a specific program. The analysis reveals that a range of ICT tools have been deployed, and further, that their use differs according to type of program. The case study suggests that rather than the proliferation of ICT tools itself, or the improved technology or bandwidth that accompanies this phenomenon, it is close attention to client business and learning objectives in program design that is driving adoption of ICT in programs.

Making use of ICT in Executive Education Programs

IMD (International Institute for Management Development) is an executive education institute that provides management development programs for middle to senior level managers. For its first few decades of existence, all of its programs were run in classrooms and meeting rooms on its campus in Lausanne, Switzerland, or at client locations. This face-to-face model of high-touch program delivery served the needs of its clients well enough for IMD over the years to be ranked among the leading executive education providers worldwide.[1]

In 1997, IMD began to use Internet and communications technologies (ICT), and especially program websites, to enhance its face-to-face delivery of executive education programs. In their earliest form, these program websites were a convenient repository for depositing program materials. However, it was quickly realized that a flexible solution that offered additional capabilities, especially in peer-to-peer communication, would allow these program websites to develop into a broader platform that would more substantially support learning objectives. Having evaluated leading solution providers' products such as Lotus LearningSpace, WebCT, and Blackboard, IMD chose to develop its own proprietary platform. This custom platform allowed some components that are mostly superfluous in an executive education environment to be eliminated entirely (e.g. grading), and afforded enhancement of others (e.g. tools to allow participants to network and collaborate virtually while not co-located).

The evolution in use of ICT at IMD

Five years on, we knew that use of this platform had increased greatly among programs. We wondered to what extent, and further, sought insight into the variety of ICT tools being used in various program components. Finally, we wondered how program directors, who are responsible for overall program design and execution (including the use of ICT in programs), went about the process of incorporating ICT when designing programs. We followed the creation of a program proposal and present this case study, to address the latter question. Our prior questions lend themselves to a more quantitative approach, and we therefore have gathered and analyzed statistics from log files, program archives, and reports, to provide a view of the use of ICT in programs.

Our overall five-year review showed steady and dramatic growth in the number of programs that have made use of ICT (table 1).

---

[1] e.g. Financial Times rankings of international non-degree executive education have ranked IMD among the top ten providers worldwide since the survey's inception in 1999.

*2002 figures Jan-July only	2002*	2001	2000	1999	1998	1997
Programs supported with ICT	36	42	32	16	2	1

Table 1: Programs Using ICT, 1997-2002

As we have noted above, initially programs used websites consisting of static pages, with content in HTML format and links for downloading content in other formats. To see the richer set of ICT currently in use, we gathered information across all programs during the first half of 2002 which were classified as blended programs, those combining face to face with virtual components (since IMD does not run completely virtual programs, while its face-to-face programs make minimal use of ICT). We examined the program websites, discussion logs, and conducted interviews with the program directors involved. These 36 blended programs represented 40% of all programs conducted by IMD during the period studied.

We classified these programs as either single module or multi-module. In this latter case, there is an opportunity for technology-mediated interaction between the face-to-face modules. We found that there was a variety of ICT tools employed directly (e.g. online chat) or embedded in program activities (e.g. online assignments), and that multi-module programs did indeed make greater use of these tools and activities (table 2).

TOOLS AND ACTIVITIES		Total	Single	Multi	Total	Single	Multi

	Electronic follow-up	2	1	1	6%	5%	6%
Average number of tools used		4	3	6			

Table 2: ICT Tools and Activities Using ICT in Programs, January – July 2002

We indeed found a broad portfolio of ICT in use in programs today: **Content library** consists of the schedule and all readings to be covered throughout the program, as well as logistics information and participant profiles. **On-line surveys** are organizational diagnostic or personal psychometric surveys administered on-line, usually in preparation for a face-to-face module that will include a debriefing of the results of the survey. **Industry analysis** is an online, highly collaborative tool that is part of a process for analyzing an industry and a company's competitive position within it. **Selected research** refers to research reports custom-selected from external commercial research providers. **Participant-generated content** refers to captured, recorded and posted participant-generated learning points and conclusions from learning activities, in electronic text, graphic, or digital image form. **Forums** are asynchronous threaded discussion forums for conversation and constructive debate.[2] **Chat rooms** are a synchronous text chat facility that can be used independently by participants (self-organized) or as part of an organized exercise. **On-line assignments** are problem-solving exercises or assignments that require results and feedback to be posted on the platform as a learning activity in the program. **Situated project work** is a current strategic project, chosen by client companies and carried out by that company's program participants to help these participants meet both learning and business objectives. **Supplementary CD-ROMs** are computer-based training programs that ensure all participants have a basic knowledge of topics such as introductory corporate finance, so that discussions can begin at a higher level than would otherwise be possible. **Community photos** are digital photos taken of participants while they are on campus, working or socializing, and posted on the platform as a reminder while participants are working at a distance. **Electronic follow-up** occurs after the program has ended. Participants share how they have applied new learning in work activities. It typically happens through web conferencing.

A Spectrum of Blended Learning – From Content to Collaboration

A further exploration of the difference between single and multi-module programs yielded more insights. We found that single-module programs tended to use fewer ICT tools and activities (average 3 per program) and were more focused on content delivery than multi-module programs, which were characterized by project work, an emphasis on collaboration, and used more tools and activities (average 6 per program). Figure 3 below contrasts the emphasis on content and collaboration in both types of programs across selected program components.

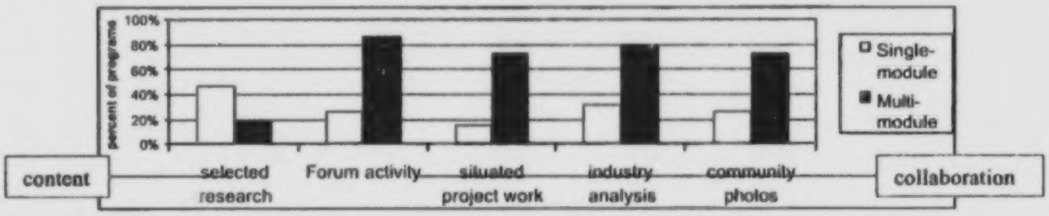

Figure 3: Content and Collaboration in Single and Multi Module Programs

Focusing on forums, we found that the average number of discussion postings in multi-module program forums was higher too, as expected given the greater opportunity to post messages between modules (table 4).

Participants and Discussion forums	Total	Single module	Multi-module
Number of Participants	1691	514	429
Number of Forum messages	2186	169	2016
Postings per participant (average)	1.29	0.33	4.70

Table 4: Average Number of Postings in Discussion Forums

Blended programs at IMD appear to fall across a spectrum. At one end are single module programs in which ICT provides convenient access to content. At the opposite end are multi-module programs in which ICT is also used for collaboration and shared learning. As Figure 5 shows, many programs fall somewhere in between.

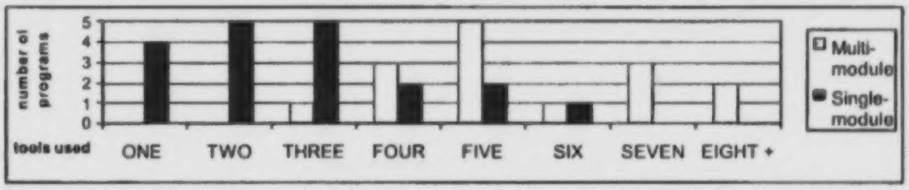

Figure 5: Number of Tools and Activities Used by Program Type

Case study: Program Proposal for a Global Financial Services Organization

With this spectrum in mind, we sought to understand how programs are designed with respect to the use of ICT tools. How does a blended program emerge? To provide some insight, we conducted a case study on a proposed design for a complex multi-modular program.

Background: Client Company's Objectives

The client company is a global financial services company. One of its key objectives is to improve its capability to innovate and implement ideas quickly across organizational boundaries. To achieve this objective, it identified its middle management as needing to develop the following: an awareness of the organization's strategic

BEST COPY AVAILABLE

imperatives; customer-driven thinking as opposed to internally generated thinking; innovative ideas and heir implementation to close the gap between the current practice and strategic imperatives; and improved effectiveness in working in global teams.

To develop its middle managers along these lines, the company decided to partner with a top-tier business school. But the traditional "week at business school" program would not be sufficient to induce deep understanding and the required behavioral change among the target group. Neither could the company spare its managers for long periods of time away from work. Tuition, travel and lodging costs would also be an issue. While the company recognized the value of taking managers out of their daily business routines to be exposed to new ways of thinking, this practice alone was seen as too abstract. Also, the difficulty of transferring, translating, and applying these new ways of thinking to business issues back at the office would remain.

Proposed Approach: "Extending the Learning" Philosophy

To address these objectives given the constraints, much of the learning would be built around participants' business projects. This project component would give meaning to the learning, and participants return to work with immediate "take home value" in the form of progress made on their projects. The use of ICT tools to support collaboration in such an approach would therefore be considered a critical part of the program.

This blended design would also afford strategic awareness, because it would allow for the longer timeframes that strategic considerations often require. Rather than instant but intangible insight, participants could develop an appreciation for strategy as grounded in their own specific business situations. Similar arguments apply to the other objectives, such as customer centred thinking, development and implementation of innovation, and global teamwork objectives. In addition, the cost-effectiveness of continuing to work together at a distance via ICT, without the travel, time, or expense required to meet in person, would allow cost and time concems to be addressed. Figure 6 illustrates how all of the components would come together.

Figure 6: Program Map

Conclusion: Learning and Business Objectives Drive ICT Usage in Programs

From an ICT point of view, the program described above is a good example of selective use of a variety of tools. The program would also have a deep and transformative impact on the organization's management, through extensive collaboration among participants and coaching by IMD through ICT. In this case, the strategic use of ICT in the program design helped achieve challenging client objectives. The proliferation of ICT tools appears to be a response to such demanding client objectives. In this case, it appears that demanding client objectives, rather than a technological focus, are driving adoption of ICT in this program. Anecdotal evidence from other programs and conversations with program directors reveals similar patterns. Thus, we would expect future technological innovations to be adopted not for their ability to replace or enhance face-to-face experiences – but for their strategic fit in meeting client objectives.

ABSTRACT

In common with most developed countries, 'New Zealand's learning environment is being transformed by new advances in technology, electronic media and the Internet.' (Beckford and Fitzsimons, 2002) The result is that teachers in this ever-changing environment have to be adaptable. This paper discusses how to keep true to pedagogical strategies whilst managing the technical issues encountered when porting courses to the web.

Our primary aim in education is to facilitate the acquisition of knowledge by our students. Whereas, in the past, lecturers could stand up at the front anddeliver a series of notes with an occasional diversion of a discussion, we teachers (tutors, lecturers) today are compared to the "edutainment" industry, where our students are very likely to switch off if not kept entertained. Our colleagues in learning psychology have long ago proved that concentration spans of today's students are reduced and that we must involve our audience. Just as we continually think of new activities in the classroom, we must think of ways to port these to online teaching. As the growth of this area explodes, we must examine the pedagogical strategies that can be used for online teaching.

INTRODUCTION

Use of the new technologies of e-communication, internet access and online courses, is having a profound affect on how society is learning (Bonk et al, 2000) Peer networks, virtual learning space and collaborative learning circles are some of the new techniques being employed. Once the initial mastery of these is achieved, the transformation to teaching online should make us more creative. It is time to look at who adapts best as an online teacher, and the techniques that will enhance the chances of success. The transition for teachers is not simple. Some tend to concentrate on the technology and forget the pedagogy of learning. Some simply hate change, and claim ideals are rarely achieved. Some teachers put a great deal of time and effort into unsuccessful ventures. 'Initial costs in staff time...high and returns are speculative.'(Swindell, 1999).

The role of the instructor is increasingly changing but the aim is the same – to make the delivery methods work for one hundred per cent of the students in one way or another. In a face-to-face class, a good teacher will watch carefully for the facial expressions of affirmation. Online, the affirmation comes through the written communication channel rather than the visual senses.

THE ROLE OF THE INSTRUCTOR

Many instructors are unsure of the online environment. According to De Fazio et al (2000, p 146), 'Academic support is often a complex role requiring a mixture of knowledge of the subject, language and study skills. In addition, there is a people or strong pastoral element that underlies the very nature of the work'. This is difficult enough in a face-to-face situation, but via a computer, 'however, retaining or attaining a sense of human interface between the teacher and the student... can be rather challenging' (De Fazio et al,2000 p 151). Instructors need to be innovative and proactive in the adoption of online strategies and the evaluation of pedagogical strategies. Their role is not just to employ new technologies, but also to maximise the achievable benefits from them. Their role is to prepare the students for the next stage in their learning.

Successful management of background tasks is important if the instructor wishes to enhance the learning. Administration of a web based course brings with it new challenging decisions about resources, tools, partners and markets. Being in love with new technology does not generate new students or class satisfaction. Good old-fashioned passionate teaching enamours students to rave about the usefulness of your course. Boring, non-passionate reading of notes drives them out of the classroom and the same disinterest to online resources results in non-participation, the silent class. If this is a base level course, the flow on effect could jeopardise the offering of higher level courses. Therefore the instructor has an obligation to tailor the use of technology to the course in question. As O'Keefe and McGrath (2000 p 378) state, 'Lecturers need to be aware of the models of teaching and learning which they implicitly or explicitly adopt, and to critically consider the role of technology both in the development of the curricula and the delivery ofthe material'. Whether online or offline, the interaction between the teacher and learner is a core element of learning. Feedback is required. 'The teacher is an important mediator in the process of constructivist academic learning' (O'Keefe and McGrath , 2000 p 377 citing Laurillard,1993), particularly in e-learning. Discussion boards have been used successfully for many years, but they are not the only tool and tend to be over used. To make this tool viable requires considerable input from the instructor. It is the instructor's role to promote collaboration, a necessary pre-requisite of on-line discussion. If students are not interested in helping others, and cannot see the benefits, the discussions will die. 'This means that a groupware application is not enough for changing the teaching-learning processes.....but simultaneous attempts to change the whole collaboration culture of the classroom are also needed.' (Lehtinen et al ,2000 p 35)

Instructors must take a lead role in the pedagogical strategies attempted in a course, but also need a mentor with whom to discuss new ideas, and preferably one with more experience in online teaching. Continual improvement can only occur if pedagogical and technical strategies that have been successful are repeated or developed further, and those that were less than successful are analysed as to their shortcomings and either discarded or reshaped. For this to happen, course documents providing reflective comments written at the time of delivery or shortly thereafter, must be available. The instructor's role in a course is preparation, delivery and most importantly, reflection, evaluation and improvement, thereby monitoring students' interest and maintaining their own.

STRATEGIES FOR FULFILMENT OF ROLES

Campbell and Hawksworth (1999) point out that the introduction to online learning is important. In our experience a conversational role taken by the instructor allows more participation by the students. Formal or directive statements like an email directing students to discuss their chosen research topic online will result in very few postings other than a declaration of the topic the student is intending to pursue. According to Green and Eves, (2000,p76), 'discussing information that the student is familiar with is essential to the establishment of confidence ... As confidence grows, students become willing to respond to the postings of others ..so the lecturer must bolster confidence during online chats and by the tone of responses to postings' . When online instructors are more interactive and spontaneous and have a genuine concern for the wellbeing of their students, this caring attitude is transferred whether in class or online and results in more interactivity.

Peer assistance should never be underestimated. Instructional conversations can be time consuming but Frequently Asked Questions (FAQs) can be stored and used again and again when appropriate. By actively encouraging the students to participate and by showing a personal interest, the instructor can facilitate the gain of significant advantages for all, by allowing the students not only to post questions, but also to provide answers. However, the postings must be monitored and mediated. The lecturer must not allow incorrect answers to go unquestioned or leave requests for help and challenges to postings to go unanswered. Weekly newsletters can be stored, edited and re-cycled where appropriate. Personalising articles and providing social reporting achieves a familial atmosphere, enhancing learning. (Campbell and Hawksworth, 1999)

One of the easiest ways to avoid overuse of any tool or strategy is to use a graph when formulating lesson plan strategies, drawing attention to usage. Variety is the key as espoused by Bonk et al (2000)

In Class	Online
Ice Breaker 8 noun activity (describe partner)	Ad hoc groups made - same exercise
Peer Feedback Roles Critical Friends	Via email Via discussion "groups"
Reading Reaction Class groups, Case Studies	Discussion Group online
Structured controversy	Whole class discussion (Points)
Brainstorming, Concept Mapping	Use of the Whiteboard (Groups)
Scavenger Hunt (library)	Use the web to get resources
Role Play (paper handouts)	Make script available to certain students. Use "avatar" names
Discussion of sound vision (resources)	Voicemail, video via net (slow) CDs or tapes (digitised)
Guest Experts (in class expensive	Use of new conferencing software

THE PRACTICE OF THE THEORY.

Current tertiary courses use a range of online facilities, with success varying from absolute success to dismal failures. Our study of one successful course with much online content, a second year paper that prepares students for customer support roles in industry, gives an insight into the use of different techniques and strategies. Originally the online resources were used to alleviate the administration load of a Co-operative Education unit, however this course was re-engineered to actively promote online learning within and outside the classroom.

In this course, initial sessions were used to familiarise the students with the tools that are required for online discussions. Blackboard (an online teaching shell) was set up to facilitate class discussions, personal diaries, file management, task completion, course notices and home pages of the students. Tasks involving collaboration with other students were assigned. These required the use of various technical equipment e.g. scanners, digital cameras and various software, the end focus being on the production of a personal home page and familiarity with the Blackboard utilities. Many different (computer) programs have been used to facilitate collaborative learning making it an important pedagogical tool. (Lehtinen et al, 1999 p16). Very early on, the students were required to conduct online discussions, even though they are physically in the same room. Here the instructor's role was critical. Digital Pictures were used so that participants could have an image of the person they were speaking to. Humour was also used, (cartoons) together with motivational snippets. A heavy focus on sharing resources found on the web was encouraged. To enhance problem solving abilities, small working groups were set up on Blackboard and each group given a similar but different brain-teaser problem. The tools within Blackboard (whiteboard and chat) allowed the participants to draw diagrams and discuss whilst being physically separated. This began in the classroom and continued remotely. The purpose of this non-assessable exercise was to encourage the metamorphosis of the student from face-to-face customer support to remote customer support, the most common implementation nowadays. Weekly tasks were set up in order to evaluate the students' ability to delegate, prioritise and organise. The students were able to view the urgency of a task and monitor/flag their own progress in private, whilst still allowing the lecturer to monitor progress. This was a practice advocated by O'Keefe and McGrath , (2000, p 375 citing Burley and McNaught,1997) 'In online courses it was necessary to retain the high degree of interaction and clarification that face-to-face tutorials provide'

The initial weeks were for the building of a learning community, which then flowed on to become online and supportive whilst they participated in their work-based placement. The use of the online support and social interaction was to raise confidence in their ability to become online commuters, giving them the skills to perform, completely online, other tasks, such as the required organisation of a training day, with no input from the lecturer until the actual training day. Monitoring of the students' communications continued, however, with the lecturer ready to step in if necessary.

All class activities and course documents were put online and visible to the students, except the Lecturer Course Portfolio document. This was a document written after (or updated) each session, providing useful information about the course and the educational context in which it was completed. The instructor's honest reflections were critical, since disasters can be as important as "golden moments". Immediately summarising a lesson overcame academic amnesia. Reading the portfolio before a session avoided pitfalls and boring repetitive teaching. Ideas on the use of appropriate online strategies linked to the student learning needs (after Laurillard), modified through experience by Mae McSporran, are as follows:

Level	Student Learning Needs	Online strategy
1	Motivation & Orientation	Clear and current information
	Information Handling Skills	FAQs, Sharing, Online resources
	Individual choices	Negotiation of topics for study
2	Independent learning Skills	Use of Personal diary, quizzes
	Developing Understanding	Collaborative tasks, problem solving exercises
